THIS PAGE BLANK (USPTO)

(54) Title: NOVEL HUMAN β_2 INTEGRIN ALPHA SUBUNIT

(57) Abstract

DNA encoding a novel human β_2 integrin α subunit polypeptide, designated α_d, is disclosed along with methods and materials for production of the same by recombinant procedures. Fusion proteins are also disclosed which include extracellular α_d protein fragments, α_d I domain fragments or full length α_d polypeptides and human immunoglobulin constant regions. Binding molecules specific for α_d are also disclosed as useful for modulating the biological activities of α_d. DNA from other species which show homology to human α_d encoding sequences are also disclosed.

- 1 -

Novel Human β_2 Integrin Alpha Subunit

This application is a continuation-in-part of U.S. Application Serial No. 08/286,889, filed August 5, 1994, which is pending, which in turn is a continuation-in-part of U.S. Application Serial No. 08/173,497, filed December

5   23, 1993, which is pending.

Field of the Invention

The present invention relates to the cloning and expression of polynucleotides encoding a novel human β_2 integrin α subunit, designated α_d, which is structurally related to the known human β_2 integrin α subunits, CD11a,

10   CD11b and CD11c. The present invention also relates to polynucleotides isolated from other species which show homology to human α_d encoding sequences.

Background of the Invention

The integrins are a class of membrane-associated molecules which actively participate in cellular adhesion. Integrins are transmembrane

15   heterodimers comprising an α subunit in noncovalent association with a β subunit. To date, at least fourteen α subunits and eight β subunits have been identified [reviewed in Springer, *Nature 346*:425-434 (1990)]. The β subunits are generally capable of association with more than one α subunit and the heterodimers sharing a common β subunit have been classified as subfamilies within the integrin

20   population.

One class of human integrins, restricted to expression in white blood cells, is characterized by a common β_2 subunit. As a result of this cell-specific expression, these integrins are commonly referred to as the leukocyte integrins, Leu-CAMs or leukointegrins. Because of the common β_2 subunit, an

25   alternative designation of this class is the β_2 integrins. The β_2 subunit (CD18) has previously been isolated in association with one of three distinct α subunits,

- 2 -

CD11a, CD11b or CD11c. The isolation of a cDNA encoding human CD18 is described in Kishimoto, *et al.*, *Cell* 48:681-690 (1987). In official WHO nomenclature, the heterodimeric proteins are referred to as CD11a/CD18, CD11b/CD18, and CD11c/CD18; in common nomenclature they are referred to

5   as LFA-1, Mac-1 or Mo1 and p150,95 or LeuM5, respectively [Cobbold, *et al.*, in *Leukocyte Typing III*, McMichael (ed), Oxford Press, p.788 (1987)]. The human β_2 integrin α subunits CD11a, CD11b and CD11c have been demonstrated to migrate under reducing condition in electrophoresis with apparent molecular weights of approximately 180 kD, 155 kD and 150 kD, respectively, and DNAs

10   encoding these subunits have been cloned [CD11a, Larson, *et al.*, *J.Cell Biol.* 108:703-712 (1989); CD11b, Corbi, *et al.*, *J.Biol.Chem.* 263:12403-12411 (1988) and CD11c, Corbi, *et al.* *EMBO J.* 6:4023-4028 (1987)]. Putative homologs of the human β_2 integrin α and β chains, defined by approximate similarity in molecular weight, have been variously identified in other species including

15   monkeys and other primates [Letvin, *et al.*, *Blood* 61:408-410 (1983)], mice [Sanchez-Madrid, *et al.*, *J.Exp.Med.* 154:1517 (1981)], and dogs [Moore, *et al.*, *Tissue Antigens* 36:211-220 (1990)].

The absolute molecular weights of presumed homologs from other species have been shown to vary significantly [see, *e.g.*, Danilenko *et al.*, *Tissue*

20   *Antigens* 40:13-21 (1992)], and in the absence of sequence information, a definitive correlation between human integrin subunits and those identified in other species has not been possible. Moreover, variation in the number of members in a protein family has been observed between different species. Consider, for example, that more IgA isotypes have been isolated in rabbits than

25   in humans [Burnett, *et al.*, *EMBO J.* 8:4041-4047 (1989) and Schneiderman, *et al.*, *Proc.Natl.Acad.Sci.(USA)* 86:7561-7565 (1989)]. Similarly, in humans, at least six variants of the metallothionine protein have been previously identified [Karin and Richards, *Nature* 299:797-802 (1982) and Varshney, *et al.*, *Mol.Cell.Biol.* 6:26-37, (1986)], whereas in the mouse, only two such variants are

- 3 -

in evidence [Searle, *et al.*, *Mol.Cell.Biol.* *4*:1221-1230 (1984)]. Therefore, existence of multiple members of a protein family in one species does not necessarily imply that corresponding family members exist in another species.

In the specific context of β_2 integrins, in dogs it has been observed that the presumed canine β_2 counterpart to the human CD18 is capable of dimer formation with as many as four potentially distinct α subunits [Danilenko, *et al.*, *supra*]. Antibodies generated by immunizing mice with canine splenocytes resulted in monoclonal antibodies which immunoprecipitated proteins tentatively designated as canine homologs to human CD18, CD11a, CD11b and CD11c based mainly on similar, but not identical, molecular weights. Another anti-canine splenocyte antibody, Ca11.8H2, recognized and immunoprecipitated a fourth α-like canine subunit also capable of association with the β_2 subunit, but having a unique molecular weight and restricted in expression to a subset of differentiated tissue macrophages. Antibodies generated by immunization of hamsters with murine dendritic cells resulted in two anti-integrin antibodies [Metlay, *et al.*, *J.Exp.Med.* *171*:1753-1771 (1990)]. One antibody, 2E6, immunoprecipitated a predominant heterodimer with subunits having approximate molecular weights of 180 kD and 90 kD in addition to minor bands in the molecular weight range of 150-160 kD. The second antibody, N418, precipitated another apparent heterodimer with subunits having approximate molecular weights of 150 kD and 90 Kd. Based on cellular adhesion blocking studies, it was hypothesized that antibody 2E6 recognized a murine counterpart to human CD18. While the molecular weight of the N418 antigen suggested recognition of a murine homolog to human CD11c/CD18, further analysis indicated that the murine antigen exhibited a tissue distribution pattern which was inconsistent with that observed for human CD11c/CD18.

The antigens recognized by the canine Ca11.8H2 antibody and the murine N418 antibody could represent a variant species (*e.g.*, a glycosylation or splice variant) of a previously identified canine or murine α subunit.

- 4 -

Alternatively, these antigens may represent unique canine and murine integrin α subunits. In the absence of specific information regarding primary structure, these alternatives cannot be distinguished.

In humans, CD11a/CD18 is expressed on all leukocytes. CD11b/CD18 and CD11c/CD18 are essentially restricted to expression on monocytes, granulocytes, macrophages and natural killer (NK) cells, but CD11c/CD18 is also detected on some B-cell types. In general, CD11a/CD18 predominates on lymphocytes, CD11b/CD18 on granulocytes and CD11c/CD18 on macrophages [see review, Arnaout, *Blood* 75:1037-1050 (1990)]. Expression of the α chains, however, is variable with regard to the state of activation and differentiation of the individual cell types [See review, Larson and Springer, *Immunol.Rev.* 114:181-217 (1990).]

The involvement of the β_2 integrins in human immune and inflammatory responses has been demonstrated using monoclonal antibodies which are capable of blocking β_2 integrin-associated cell adhesion. For example, CD11a/CD18, CD11b/CD18 and CD11c/CD18 actively participate in natural killer (NK) cell binding to lymphoma and adenocarcinoma cells [Patarroyo, *et al.*, *Immunol.Rev.* 114:67-108 (1990)], granulocyte accumulation [Nourshargh, *et al.*, *J.Immunol.* 142:3193-3198 (1989)], granulocyte-independent plasma leakage [Arfors, *et al.*, *Blood* 69:338-340 (1987)], chemotactic response of stimulated leukocytes [Arfors, *et al.*, *supra*] and leukocyte adhesion to vascular endothelium [Price, *et al.*, *J.Immunol.* 139:4174-4177 (1987) and Smith, *et al.*, *J.Clin.Invest.* 83:2008-2017 (1989)]. The fundamental role of β_2 integrins in immune and inflammatory responses is made apparent in the clinical syndrome referred to as leukocyte adhesion deficiency (LAD), wherein clinical manifestations include recurrent and often life threatening bacterial infections. LAD results from heterogeneous mutations in the β_2 subunit [Kishimoto, *et al.*, *Cell* 50:193-202 (1987)] and the severity of the disease state is proportional to the degree of the

- 5 -

deficiency in β_2 subunit expression. Formation of the complete integrin heterodimer is impaired by the β_2 mutation [Kishimoto, _et al., supra_].

Interestingly, at least one antibody specific for CD18 has been shown to inhibit human immunodeficiency virus type-1 (HIV-1) syncytia formation _in vitro_, albeit the exact mechanism of this inhibition is unclear [Hildreth and Orentas, _Science 244_:1075-1078 (1989)]. This observation is consistent with the discovery that a principal counterreceptor of CD11a/CD18, ICAM-1, is also a surface receptor for the major group of rhinovirus serotypes [Greve, _et al., Cell 56_:839 (1989)].

The significance of β_2 integrin binding activity in human immune and inflammatory responses underscores the necessity to develop a more complete understanding of this class of surface proteins. Identification of yet unknown members of this subfamily, as well as their counterreceptors, and the generation of monoclonal antibodies or other soluble factors which can alter biological activity of the β_2 integrins will provide practical means for therapeutic intervention in β_2 integrin-related immune and inflammatory responses.

Brief Description of the Invention

In one aspect, the present invention provides novel purified and isolated polynucleotides (_e.g.,_ DNA and RNA transcripts, both sense and anti-sense strands) encoding a novel human β_2 integrin α subunit, α_d, and variants thereof (_i.e.,_ deletion, addition or substitution analogs) which possess binding and/or immunological properties inherent to α_d. Preferred DNA molecules of the invention include cDNA, genomic DNA and wholly or partially chemically synthesized DNA molecules. A presently preferred polynucleotide is the DNA as set forth in SEQ ID NO: 1, encoding the polypeptide of SEQ ID NO: 2. Also provided are recombinant plasmid and viral DNA constructions (expression constructs) which include α_d encoding sequences, wherein the α_d encoding

- 6 -

sequence is operatively linked to a homologous or heterologous transcriptional regulatory element or elements.

Also provided by the present invention are isolated and purified mouse and rat polynucleotides which exhibit homology to polynucleotides encoding human α_d. A preferred mouse polynucleotide is set forth in SEQ ID NO: 52; a preferred rat polynucleotide is set forth in SEQ ID NO: 54.

As another aspect of the invention, prokaryotic or eukaryotic host cells transformed or transfected with DNA sequences of the invention are provided which express α_d polypeptide or variants thereof. Host cells of the invention are particularly useful for large scale production of α_d polypeptide, which can be isolated from either the host cell itself or from the medium in which the host cell is grown. Host cells which express α_d polypeptide on their extracellular membrane surface are also useful as immunogens in the production of α_d-specific antibodies. Preferably, host cells transfected with α_d will be co-transfected to express a β_2 integrin subunit in order to allow surface expression of the heterodimer.

Also provided by the present invention are purified and isolated α_d polypeptides, fragments and variants thereof. Preferred α_d polypeptides are as set forth in SEQ ID NO: 2. Novel α_d products of the invention may be obtained as isolates from natural sources, but, along with α_d variant products, are preferably produced by recombinant procedures involving host cells of the invention. Completely glycosylated, partially glycosylated and wholly de-glycosylated forms of the α_d polypeptide may be generated by varying the host cell selected for recombinant production and/or post-isolation processing. Variant α_d polypeptides of the invention may comprise water soluble and insoluble α_d polypeptides including analogs wherein one or more of the amino acids are deleted or replaced: (1) without loss, and preferably with enhancement, of one or more biological activities or immunological characteristics specific for α_d; or (2) with specific disablement of a particular ligand/receptor binding or signalling

- 7 -

function.   Fusion polypeptides are also provided, wherein α_d amino acid sequences are expressed contiguously with amino acid sequences from other polypeptides.   Such fusion polypeptides may possess modified biological, biochemical, and/or immunological properties in comparison to wild-type α_d.

5   Analog polypeptides including additional amino acid (e.g., lysine or cysteine) residues that facilitate multimer formation are contemplated.

Also comprehended by the present invention are polypeptides and other non-peptide molecules which specifically bind to α_d. Preferred binding molecules include antibodies (e.g., monoclonal and polyclonal antibodies),

10   counterreceptors (e.g., membrane-associated and soluble forms) and other ligands (e.g., naturally occurring or synthetic molecules), including those which competitively bind α_d in the presence of α_d monoclonal antibodies and/or specific counterreceptors. Binding molecules are useful for purification of α_d polypeptides and identifying cell types which express α_d. Binding molecules are also useful for

15   modulating (i.e., inhibiting, blocking or stimulating) of in vivo binding and/or signal transduction activities of α_d.

Assays to identify α_d binding molecules are also provided, including immobilized ligand binding assays, solution binding assays, scintillation proximity assays, di-hybrid screening assays, and the like.

20   In vitro assays for identifying antibodies or other compounds that modulate the activity of α_d may involve, for example, immobilizing α_d or a natural ligand to which α_d binds, detectably labelling the nonimmobilized binding partner, incubating the binding partners together and determining the effect of a test compound on the amount of label bound wherein a reduction in the label

25   bound in the presence of the test compound compared to the amount of label bound in the absence of the test compound indicates that the test agent is an inhibitor of α_d binding.

Another type of assay for identifying compounds that modulate the interaction between α_d and a ligand involves immobilizing α_d or a fragment

- 8 -

thereof on a solid support coated (or impregnated with) a fluorescent agent, labelling the ligand with a compound capable of exciting the fluorescent agent, contacting the immobilized α_d with the labelled ligand in the presence and absence of a putative modulator compound, detecting light emission by the fluorescent

5   agent, and identifying modulating compounds as those compounds that affect the emission of light by the fluorescent agent in comparison to the emission of light by the fluorescent agent in the absence of a modulating compound. Alternatively, the α_d ligand may be immobilized and α_d may be labelled in the assay.

         Yet another method contemplated by the invention for identifying

10   compounds that modulate the interaction between α_d and a ligand involves transforming or transfecting appropriate host cells with a DNA construct comprising a reporter gene under the control of a promoter regulated by a transcription factor having a DNA-binding domain and an activating domain, expressing in the host cells a first hybrid DNA sequence encoding a first fusion

15   of part or all of α_d and either the DNA binding domain or the activating domain of the transcription factor, expressing in the host cells a second hybrid DNA sequence encoding part or all of the ligand and the DNA binding domain or activating domain of the transcription factor which is not incorporated in the first fusion, evaluating the effect of a putative modulating compound on the interaction

20   between α_d and the ligand by detecting binding of the ligand to α_d in a particular host cell by measuring the production of reporter gene product in the host cell in the presence or absence of the putative modulator, and identifying modulating compounds as those compounds altering production of the reported gene product in comparison to production of the reporter gene product in the absence of the

25   modulating compound. Presently preferred for use in the assay are the *lexA* promoter, the *lexA* DNA binding domain, the GAL4 transactivation domain, the *lacZ* reporter gene, and a yeast host cell.

         A modified version of the foregoing assay may be used in isolating a polynucleotide encoding a protein that binds to α_d by transforming or

- 9 -

transfecting appropriate host cells with a DNA construct comprising a reporter gene under the control of a promoter regulated by a transcription factor having a DNA-binding domain and an activating domain, expressing in the host cells a first hybrid DNA sequence encoding a first fusion of part or all of α_d and either

5   the DNA binding domain or the activating domain of the transcription factor, expressing in the host cells a library of second hybrid DNA sequences encoding second fusions of part or all of putative α_d binding proteins and the DNA binding domain or activating domain of the transcription factor which is not incorporated in the first fusion, detecting binding of an α_d binding protein to α_d in a particular

10   host cell by detecting the production of reporter gene product in the host cell, and isolating second hybrid DNA sequences encoding α_d binding protein from the particular host cell.

        Hybridoma cell lines which produce antibodies specific for α_d are also comprehended by the invention. Techniques for producing hybridomas which

15   secrete monoclonal antibodies are well known in the art. Hybridoma cell lines may be generated after immunizing an animal with purified α_d, variants of α_d or cells which express α_d or a variant thereof on the extracellular membrane surface. Immunogen cell types include cells which express α_d *in vivo*, or transfected prokaryotic or eukaryotic cell lines which normally do not normally express α_d

20   *in vivo*.

        The value of the information contributed through the disclosure of the DNA and amino acid sequences of α_d is manifest. In one series of examples, the disclosed α_d CDNA sequence makes possible the isolation of the human α_d genomic DNA sequence, including transcriptional control elements for the

25   genomic sequence. Identification of α_d allelic variants and heterologous species (*e.g.*, rat or mouse) DNAs is also comprehended. Isolation of the human α_d genomic DNA and heterologous species DNAs can be accomplished by standard DNA/DNA hybridization techniques, under appropriately stringent conditions, using all or part of the α_d cDNA sequence as a probe to screen an appropriate

- 10 -

library.   Alternatively, polymerase chain reaction (PCR) using oligonucleotide primers that are designed based on the known cDNA sequence can be used to amplify and identify genomic α_d DNA sequences.   Synthetic DNAs encoding the α_d polypeptide, including fragments and other variants thereof, may be produced by conventional synthesis methods.

DNA sequence information of the invention also makes possible the development, by homologous recombination or "knockout" strategies [see, e.g., Kapecchi, Science 244:1288-1292 (1989)], to produce rodents that fail to express a functional α_d polypeptide or that express a variant α_d polypeptide.   Such rodents are useful as models for studying the activities of α_d and α_d modulators in vivo.

DNA and amino acid sequences of the invention also make possible the analysis of α_d epitopes which actively participate in counterreceptor binding as well as epitopes which may regulate, rather than actively participate in, binding.   Identification of epitopes which may participate in transmembrane signal transduction is also comprehended by the invention.

DNA of the invention is also useful for the detection of cell types which express α_d polypeptide.   Standard DNA/RNA hybridization techniques which utilize α_d DNA to detect α_d RNA may be used to determine the constitutive level of α_d transcription within a cell, as well as changes in the level of transcription in response to internal or external agents.   Identification of agents which modify transcription and/or translation of α_d can, in turn, be assessed for potential therapeutic or prophylactic value.   DNA of the invention also makes possible in situ hybridization of α_d DNA to cellular RNA to determine the cellular localization of α_d specific messages within complex cell populations and tissues.

DNA of the invention is also useful for identification of non-human polynucleotide sequences which display homology to human α_d sequences.   Possession of non-human α_d DNA sequences permits development of animal models (including, for example, transgenic models) of the human system.

- 11 -

As another aspect of the invention, monoclonal or polyclonal antibodies specific for α_d may be employed in immunohistochemical analysis to localize α_d to subcellular compartments or individual cells within tissues. Immunohistochemical analyses of this type are particularly useful when used in

5   combination with *in situ* hybridization to localize both α_d mRNA and polypeptide products of the α_d gene.

Identification of cell types which express α_d may have significant ramifications for development of therapeutic and prophylactic agents. It is anticipated that the products of the invention related to α_d can be employed in the

10   treatment of diseases wherein macrophages are an essential element of the disease process. Animal models for many pathological conditions associated with macrophage activity have been described in the art. For example, in mice, macrophage recruitment to sites of both chronic and acute inflammation is reported by Jutila, *et al.*, *J.Leukocyte Biol.* 54:30-39 (1993). In rats, Adams, *et*

15   *al.*, [*Transplantation 53*:1115-1119(1992) and *Transplantation 56*:794-799 (1993)] describe a model for graft arteriosclerosis following heterotropic abdominal cardiac allograft transplantation. Rosenfeld, *et al.*, [*Arteriosclerosis 7*:9-23 (1987) and *Arteriosclerosis 7*:24-34 (1987)] describe induced atherosclerosis in rabbits fed a cholesterol supplemented diet. Hanenberg, *et al.*, [*Diabetologia 32*:126-134

20   (1989)] report the spontaneous development of insulin-dependent diabetes in BB rats. Yamada *et al.*, [*Gastroenterolgy 104*:759-771 (1993)] describe an induced inflammatory bowel disease, chronic granulomatous colitis, in rats following injections of streptococcal peptidoglycan-polysaccharide polymers. Cromartie, *et al.*, [*J.Exp.Med. 146*:1585-1602 (1977)] and Schwab, *et al.*, [*Infection and*

25   *Immunity 59*:4436-4442 (1991)] report that injection of streptococcal cell wall protein into rats results in an arthritic condition characterized by inflammation of peripheral joints and subsequent joint destruction. Finally, Huitinga, *et al.*, [*Eur.J.Immunol 23*:709-715 (1993) describe experimental allergic encephalomyelitis, a model for multiple sclerosis, in Lewis rats. In each of these

- 12 -

models, α_d antibodies, other α_d binding proteins, or soluble forms of α_d are utilized to attenuate the disease state, presumably through inactivation of macrophage activity.

5   Pharmaceutical compositions for treatment of these and other disease states are provided by the invention. Pharmaceutical compositions are designed for the purpose of inhibiting interaction between α_d and its ligand(s) and include various soluble and membrane-associated forms of α_d (comprising the entire α_d polypeptide, or fragments thereof which actively participate in α_d binding), soluble and membrane-associated forms of α_d binding proteins

10   (including antibodies, ligands, and the like), intracellular or extracellular modulators of α_d binding activity, and/or modulators of α_d and/or α_d-ligand polypeptide expression, including modulators of transcription, translation, post-translational processing and/or intracellular transport. The invention also comprehends methods for treatment of disease states in which α_d binding is

15   implicated, wherein a patient suffering from said disease state is provided an amount of a pharmaceutical composition of the invention sufficient to modulate levels of α_d binding. The method of treatment of the invention is applicable to disease states such as, but not limited to, Type I diabetes, atherosclerosis, multiple sclerosis, asthma, psoriasis, and rheumatoid arthritis.

20   Brief Description of the Drawing

         Numerous other aspects and advantages of the present invention will be apparent upon consideration of the following description thereof, reference being made to the drawing wherein:

         Figure 1A through 1D comprises an alignment of the human amino

25   acid sequences of CD11b (SEQ ID NO: 3), CD11c (SEQ ID NO: 4) and α_d (SEQ ID NO: 2).

- 13 -

Detailed Description of the Invention

The present invention is illustrated by the following examples relating to the isolation of a cDNA clone encoding α_d from a human spleen cDNA library. More particularly, Example 1 illustrates the use of anti-canine α_{TM1} antibody in an attempt to detect a homologous human protein. Example 2 details purification of canine α_{TM1} and N-terminal sequencing of the polypeptide to design oligonucleotide primers for PCR amplification of the canine α_{TM1} gene. Example 3 addresses large scale purification of canine α_{TM1} for internal sequencing in order to design additional PCR primers. Example 4 describes use of the PCR and internal sequence primers to amplify a fragment of the canine α_{TM1} gene. Example 5 addresses cloning of the human α_d-encoding cDNA sequence. Example 6 describes Northern blot hybridization analysis of human tissues and cells for expression of α_d mRNA. Example 7 details the construction of human α_d expression plasmids and transfection of COS cells with the resulting plasmids. Example 8 addresses ELISA analysis of α_d expression in transfected COS cells. Example 9 describes FACS analysis of COS cells transfected with human α_d expression plasmids. Example 10 addresses immunoprecipitation of CD18 in association with α_d in co-transfected COS cells. Example 11 relates to stable transfection of α_d expression constructs in Chinese hamster ovary cells. Example 12 addresses CD18-dependent binding of α_d to the intercellular adhesion molecule, ICAM-R. Example 13 describes scintillation proximity screening assays to identify inhibitors of α_d ligand/anti-ligand binding interactions. Example 14 addresses construction of expression plasmids which encode soluble forms of α_d. Example 15 relates to production of α_d-specific monoclonal antibodies. Example 16 describes analysis of α_d tissue distribution using polyclonal antiserum. Example 17 describes isolation of rat cDNA sequences which show homology to human α_d gene sequences. Example 18 relates to construction of rat α_d I domain expression plasmids, including I domain/IgG fusion proteins, and production of monoclonal antibodies to I domain fusion

- 14 -

proteins. Example 19 addresses isolation of mouse cDNA sequences which show homology to human α_d gene sequences. Example 20 describes isolation of additional mouse α_d cDNA clones used for conformational sequence analysis. Example 21 relates to *in situ* hybridization analysis of various mouse tissues to

5   determine tissue and cell specific expression of the putative mouse homolog to human α_d. Example 22 describes generation of expression constructs which encode the putative mouse homolog of human α_d. Example 23 addresses design of a "knock-out" mouse wherein the gene encoding the putative mouse homolog of human α_d is disrupted. Example 24 describes isolation of rabbit cDNA clones

10   which show homology to human α_d encoding sequences. Example 25 describes animal models which resemble human disease states wherein modulation of α_d is assayed for therapeutic capabilities.

Example 1

Attempt to Detect a Human Homolog of Canine α_{TM1}

15   The monoclonal antibody Ca11.8H2 [Moore, et al., *supra*] specific for canine α_{TM1} was tested for cross-reactivity on human peripheral blood leukocytes in an attempt to identify a human homolog of canine α_{TM1}. Cell preparations (typically 1 x 10^6 cells) were incubated with undiluted hybridoma supernatant or a purified mouse IgG-negative control antibody (10 μg/ml) on ice

20   in the presence of 0.1% sodium azide. Monoclonal antibody binding was detected by subsequent incubation with FITC-conjugated horse anti-mouse IgG (Vector Laboratories, Burlingame, CA) at 6 μg/ml. Stained cells were fixed with 2% w/v paraformaldehyde in phosphate buffered saline (PBS) and were analyzed with a Facstar Plus fluorescence-activated cell sorter (Becton Dickinson, Mountain View,

25   CA). Typically, 10,000 cells were analyzed using logarithmic amplification for fluorescence intensity.

                     The results indicated that Ca11.8H2 did not cross-react with surface proteins expressed on human peripheral blood leukocytes, while the control cells,

- 15 -

neoplastic canine peripheral blood lymphocytes, were essentially all positive for α_{TM1}.

Because the monoclonal antibody Ca11.8H2 specific for the canine α subunit did not cross react with a human homolog, isolation of canine α_{TM1}

5 DNA was deemed a necessary prerequisite to isolate a counterpart human gene if one existed.

Example 2

Affinity Purification Of Canine α_{TM1} For N-Terminal Sequencing

Canine α_{TM1} was affinity purified in order to determine N-terminal amino acid sequences for oligonucleotide probe/primer design. Briefly, anti-α_{TM1}

10 monoclonal antibody Ca11.8H2 was coupled to Affigel 10 chromatographic resin (BioRad, Hercules, CA) and protein was isolated by specific antibody-protein interaction. Antibody was conjugated to the resin, according to the BioRad suggested protocol, at a concentration of approximately 5 mg antibody per ml of resin. Following the conjugation reaction, excess antibody was removed and the

15 resin blocked with three volumes of 0.1 M ethanolamine. The resin was then washed with thirty column volumes of phosphate buffered saline (PBS).

Twenty-five grams of a single dog spleen were homogenized in 250 ml of buffer containing 0.32 M sucrose in 25 mM Tris-HCl, Ph 8.0, with

20 protease inhibitors. Nuclei and cellular debris were pelleted with centrifugation at 1000 g for 15 minutes. Membranes were pelleted from the supernatant with centrifugation at 100,000 g for 30 minutes. The membrane pellet was resuspended in 200 ml lysis buffer (50 mM NaCl, 50 mM borate, pH 8.0, with 2% NP-40) and incubated for 1 hour on ice. Insoluble material was then pelleted

25 by centrifugation at 100,000 g for 60 minutes. Ten milliliters of the cleared lysate were transferred to a 15 ml polypropylene tube with 0.5 ml Ca11.8H2-conjugated Affigel 10 resin described above. The tube was incubated overnight at 4°C with rotation and the resin subsequently washed with 50 column volumes

- 16 -

D-PBS. The resin was then transferred to a microfuge tube and boiled for ten minutes in 1 ml Laemmli (non-reducing) sample buffer containing 0.1 M Tris-HCl, pH 6.8, 2% SDS, 20% glycerol and 0.002% bromophenol blue. The resin was pelleted by centrifugation and discarded; the supernatant was treated with

5   1/15 volume β-mercaptoethanol (Sigma, St. Louis, MO) and run on a 7% polyacrylamide gel. The separated proteins were transferred to Immobilon PVDF membrane (Millipore, Bedford, MA) as follows.

          The gels were washed once in deionized, Millipore-filtered water and equilibrated for 15-45 minutes in 10 mM 3-[cyclohexylamino]-1-

10   propanesulfonic acid (CAPS) transfer buffer, pH 10.5, with 10% methanol. Immobilon membranes were moistened with methanol, rinsed with filtered water, and equilibrated for 15-30 minutes in CAPS transfer buffer. The initial transfer was carried out using a Biorad transfer apparatus at 70 volts for 3 hours. The Immobilon membrane was removed after transfer and stained in filtered 0.1%

15   R250 Coomassie stain for 10 minutes. Membranes were destained in 50% methanol/10% acetic acid three times, ten minutes each time. After destaining, the membranes were washed in filtered water and air-dried.

          Protein bands of approximately 150 kD, 95 kD, 50 kD and 30 kD were detected. Presumably the 50 kD and 30 kD bands resulted from antibody

20   contamination. N-terminal sequencing was then attempted on both the 150 kD and 95 kD bands, but the 95 kD protein was blocked, preventing sequencing. The protein band of 150 kD was excised from the membrane and directly sequenced with an Applied Biosystems (Foster City, CA) Model 473A protein sequencer according to the manufacturer's instructions. The resulting amino acid

25   sequence is set in SEQ ID NO: 5 using single letter amino acid designations.

               FNLDVEEPMVFQ   (SEQ ID NO: 5)

- 17 -

The identified sequence included the FNLD sequence characteristic of α subunits of the integrin family [Tamura, *et al.*, *J.Cell.Biol.* *111*:1593-1604 (1990)].

Primer Design and Attempt to Amplify Canine α_{TM1} Sequences

From the N-terminal sequence information, three oligonucleotide probes were designed for hybridization: a) "Tommer," a fully degenerate oligonucleotide; b) "Patmer," a partially degenerate oligonucleotide; and c) "Guessmer," a nondegenerate oligonucleotide based on mammalian codon usage. These probes are set out below as SEQ ID NOS: 6, 7 and 8, respectively. Nucleic acid symbols are in accordance with 37 C.F.R. §1.882 for these and all other nucleotide sequences herein.

5´-TTYAAYYTGGAYGTNGARGARCCNATGGTNTTYCA-3´(SEQ ID NO: 6)
5´-TTCAACCTGGACGTGGAGGAGCCCATGGTGTTCCAA(SEQ ID NO: 7)
5´-TTCAACCTGGACGTNGAASANCCCATGGTCTTCCAA-(SEQ ID NO: 8)

Based on sequencing data, no relevant clones were detected using these oligonucleotides in several low stringency hybridizations to a canine spleen/peripheral blood macrophage cDNA library cloned into λZAP (Stratagene, La Jolla, CA).

Four other oligonucleotide primers, designated 5´Deg, 5´Spec, 3´Deg and 3´Spec (as set out in SEQ ID NOS: 9, 10, 11 and 12, respectively, wherein Deg indicates degenerate and Spec indicates non-degenerate) were subsequently designed based on the deduced N-terminal sequence for attempts to amplify canine α_{TM1} sequences by PCR from phage library DNA purified from plate lysates of the Stratagene library described above.

5´-TTYAAYYTNGAYGTNGARGARCC-3´   (SEQ ID NO: 9)
5´-TTYAAYYTGGACGTNGAAGA-3´   (SEQ ID NO: 10)

- 18 -

5´-TGRAANACCATNGGYTC-3´   (SEQ ID NO: 11)

5´-TTGGAAGACCATNGGYTC-3´   (SEQ ID NO: 12)

       The α_{TM1} oligonucleotide primers were paired with T3 or T7
vector primers, as set out in SEQ ID NOS: 13 and 14, respectively, which

5   hybridize to sequences flanking the polylinker region in the Bluescript phagemid
found in λZAP.

5´-ATTAACCCTCACTAAAG-3´   (SEQ ID NO: 13)

5´-AATACGACTCACTATAG-3´   (SEQ ID NO: 14)

       The PCR amplification was carried out in *Taq* buffer (Boehringer Mannheim,

10   Indianapolis, IN) containing magnesium with 150 ng of library DNA, 1 µg of
each primer, 200 µM dNTPs and 2.5 units *Taq* polymerase (Boehringer
Mannheim) and the products were separated by electrophoresis on a 1% agarose
gel in Tris-Acetate-EDTA (TAE) buffer with 0.25 µg/ml ethidium bromide. DNA
was transferred to a Hybond (Amersham, Arlington Heights, IL) membrane by

15   wicking overnight in 10X SSPE. After transfer, the immobilized DNA was
denatured with 0.5 M NaOH with 0.6 M NaCl, neutralized with 1.0 M Tris-HCl,
pH 8.0, in 1.5 M NaCl, and washed with 2X SSPE before UV crosslinking with
a Stratalinker (Stratagene) crosslinking apparatus. The membrane was incubated
in prehybridization buffer (5X SSPE, 4X Denhardts, 0.8% SDS, 30% formamide)

20   for 2 hr at 50°C with agitation.

       Oligonucleotide probes 5´Deg, 5´Spec, 3´Deg and 3´Spec (SEQ
ID NOS: 9, 10, 11 and 12, respectively) were labeled using a Boehringer
Mannheim kinase buffer with 100-300 µCi γP^{32}-dATP and 1-3 units of
polynucleotide kinase for 1-3 hr at 37°C. Unincorporated label was removed with

25   Sephadex G-25 fine (Pharmacia, Piscataway, NJ) chromatography using 10 mM
Tris-HCl, pH 8.0, 1 mM EDTA (TE) buffer and the flow-through added directly
to the prehybridization solution. Membranes were probed for 16 hr at 42°C with

- 19 -

agitation and washed repeatedly, with a final stringency wash of 1X SSPE/0.1%
SDS at 50° for 15 min. The blot was then exposed to Kodak X-Omat AR film
for 1-4 hours at -80°C.

5   The oligonucleotides 5′Deg, 5′Spec, 3′Deg and 3′Spec only
hybridized to PCR products from the reactions in which they were used as
primers and failed to hybridize as expected to PCR products from the reactions
in which they were not used as primers. Thus, it was concluded that none of the
PCR products were specific for α_{TM1} because no product hybridized with all of
the appropriate probes.

10   Example 3

Large Scale Affinity Purification Of Canine α_{TM1} For Internal Sequencing

In order to provide additional amino acid sequence for primer
design, canine α_{TM1} was purified for internal sequencing. Three sections of
frozen spleen (approximately 50 g each) and frozen cells from two partial spleens
15   from adult dogs were used to generate protein for internal sequencing. Fifty
grams of spleen were homogenized in 200-300 ml borate buffer with a Waring
blender. The homogenized material was diluted with 1 volume of buffer
containing 4% NP-40, and the mixture then gently agitated for at least one hour.
The resulting lysate was cleared of large debris by centrifugation at 2000 g for 20
20   min, and then filtered through either a Corning (Corning, NY) prefilter or a
Corning 0.8 micron filter. The lysate was further clarified by filtration through
the Corning 0.4 micron filter system.

Splenic lysate and the antibody-conjugated Affigel 10 resin
described in Example 2 were combined at a 150:1 volume ratio in 100 ml aliquots
25   and incubated overnight at 4°C with rocking. The lysate was removed after
centrifugation at 1000 g for 5 minutes, combined with more antibody-conjugated
Affigel 10 resin and incubated overnight as above. The absorbed resin aliquots
were then combined and washed with 50 volumes D-PBS/0.1% Tween 20 and the

- 20 -

resin transferred to a 50 ml Biorad column. Adsorbed protein was eluted from the resin with 3-5 volumes of 0.1 M glycine (pH 2.5); fractions of approximately 900 μl were collected and neutralized with 100 μl 1 M Tris buffer, pH 8.0. Aliquots of 15 μl were removed from each fraction and boiled in an equal volume of 2X Laemmli sample buffer with 1/15 volume 1 M dithiothreitol (DTT). These samples were electrophoresed on 8% Novex (San Diego, CA) polyacrylamide gels and visualized either by Coomassie stain or by silver stain using a Daiichi kit (Enprotech, Natick, MA) according to the manufacturer's suggested protocol. Fractions which contained the largest amounts of protein were combined and concentrated by vacuum. The remaining solution was diluted by 50% with reducing Laemmli sample buffer and run on 1.5 mm 7% polyacrylamide gels in Tris-glycine/SDS buffer. Protein was transferred from the gels to Immobilon membrane by the procedure described in Example 2 using the Hoefer transfer apparatus.

The protein bands corresponding to canine α_{TM1} were excised from 10 PVDF membranes and resulted in approximately 47 μg total protein. The bands were destained in 4 ml 50% methanol for 5 minutes, air dried and cut into 1 x 2 mm pieces. The membrane pieces were submerged in 2 ml 95% acetone at 4°C for 30 minutes with occasional vortexing and then air dried.

Prior to proteolytic cleavage of the membrane bound protein, 3 mg of cyanogen bromide (CNBr) (Pierce, Rockford, IL) were dissolved in 1.25 ml 70% formic acid. This solution was then added to a tube containing the PVDF membrane pieces and the tube incubated in the dark at room temperature for 24 hours. The supernatant (S1) was then removed to another tube and the membrane pieces washed with 0.25 ml 70% formic acid. This supernatant (S2) was removed and added to the previous supernatant (S1). Two milliliters of Milli Q water were added to the combined supernatants (S1 and S2) and the solution lyophilized. The PVDF membrane pieces were dried under nitrogen and extracted again with 1.25 ml 60% acetonitrile, 0.1% tetrafluoroacetic acid (TFA) at 42°C for 17 hours.

- 21 -

This supernatant (S3) was removed and the membrane pieces extracted again with 1.0 ml 80% acetonitrile with 0.08% TFA at 42°C for 1 hour. This supernatant (S4) was combined with the previous supernatants (S1, S2 and S3) and vacuum dried.

5   The dried CNBr fragments were then dissolved in 63 μl 8 M urea, 0.4 M NH_4HCO_3. The fragments were reduced in 5 μl 45 mM dithiothreitol (DTT) and subsequently incubated at 50°C for 15 minutes. The solution was then cooled to room temperature and the fragments alkylated by adding 5 μl 100 mM iodoacetamide (Sigma, St. Louis, MO). Following a 15 minute incubation at

10   room temperature, the sample was diluted with 187 μl Milli Q water to a final urea concentration of 2.0 M. Trypsin (Worthington, Freehold, NJ) was then added at a ratio of 1:25 (w:w) of enzyme to protein and the protein digested for 24 hours at 37°C. Digestion was terminated with addition of 30 μl TFA.

The protein fragments were then separated with high performance

15   liquid chromatography (HPLC) on a Waters 625 LC system (Millipore, Milford, MA) using a 2.1 x 250 mm, 5 micron Vydac C-18 column (Vydac, Hesperia, CA) equilibrated in 0.05% TFA and HPLC water (buffer A). The peptides were eluted with increasing concentration of 80% acetonitrile in 0.04% TFA (buffer B) with a gradient of 38-75% buffer B for 65-95 minutes and 75-98% buffer B for

20   95-105 minutes. Peptides were fractionated at a flow rate of 0.2 ml/minute and detected at 210 nm.

Following fractionation, the amino acid sequence of the peptides was analyzed by automated Edman degradation performed on an Applied Biosystems Model 437A protein sequencer using the manufacturer's standard

25   cycles and the Model 610A Data Analysis software program, Version 1.2.1. All sequencing reagents were supplied by Applied Biosystems. The amino acid sequences of seven of the eight internal fragments are set out below wherein "X" indicates the identity of the amino acid was not certain.

- 22 -

Example 4

PCR Cloning Of A Canine α_{TM1} Fragment

The 5´ portion of the canine α_{TM1} gene was amplified from double-stranded canine splenic cDNA by PCR.

A. Generation of Double Stranded Canine Spleen cDNA

One gram of frozen material from a juvenile dog spleen was ground in liquid nitrogen on dry ice and homogenized in 20 ml RNA-Stat 60 buffer (Tel-Test B, Inc, Friendswood, TX). Four ml chloroform were added, and the solution extracted by centrifugation at 12,000 g for 15 minutes. RNA was precipitated from the aqueous layer with 10 ml ethanol. Poly A$^+$ RNA was then selected on Dynal Oligo dT Dynabeads (Dynal, Oslo, Norway). Five aliquots of 100 μg total RNA were combined and diluted with an equal volume of 2X binding

- 23 -

buffer (20 mM Tris-HCl, pH 7.5, 1.0 M LiCl, 1 mM EDTA, 0.1% SDS). RNA was then incubated 5 minutes with the Oligo dT Dynabeads (1.0 ml or 5 mg beads for all the samples). Beads were washed with buffer containing 10 mM Tris-HCl, pH 7.5, 0.15 M LiCl, 1 mM EDTA and 0.1% SDS, according to the manufacturer's suggested protocol prior to elution of poly A^+ mRNA with 2 mM EDTA, pH 7.5. Double-stranded cDNA was then generated using the eluted poly A^+ mRNA and the Boehringer Mannheim cDNA Synthesis Kit according to the manufacturer's suggested protocol.

B. Isolation of a Partial Canine α_{TM1} cDNA

Oligonucleotide primers 5'Deg (SEQ ID NO: 9) and p4(R) (SEQ ID NO: 23) were employed in a standard PCR reaction using 150 ng double-stranded cDNA, 500 ng of each primer, 200 μM dNTPs and 1.5 units Taq polymerase (Boehringer Mannheim) in Taq buffer (Boehringer Mannheim) with magnesium. The resulting products (1 μl of the original reaction) were subjected to a second round of PCR with the same primers to increase product yield. This band was eluted from a 1% agarose gel onto Schleicher & Schuell (Keene, NH) NA45 paper in a buffer containing 10 mM Tris-HCl, pH 8, 1 mM EDTA, 1.5 M NaCl at 65°C, precipitated, and ligated into the pCR^{tm}II vector (Invitrogen, San Diego, CA) using the TA cloning kit (Invitrogen) and the manufacturer's suggested protocol. The ligation mixture was transformed by electroporation into XL-1 Blue bacteria (Stratagene). One clone, 2.7, was determined to contain sequences corresponding to α_{TM1} peptide sequences which were not utilized in design of the primers.

Sequencing was performed with an Applied Biosystems 373A DNA sequencer (Foster City, CA) with a Dye-deoxy terminator cycle sequence kit (ABI) in which fluorescent-labeled dNTPs were incorporated in an asymmetric PCR reaction [McCabe, "Production of Single Stranded DNA by Asymmetric PCR," in PCR Protocols: A Guide to Methods and Applications, Innis, et al.

- 24 -

(eds.) pp. 76-83 Academic Press: New York (1990)] as follows. Samples were held at 96°C for 4 minutes and subjected to 25 cycles of the step sequence: 96°C, for 15 seconds; 50°C for 1 second; 60°C for 4 minutes. Sequence data was automatically down-loaded into sample files on the computer that included

5   chromatogram and text files. The sequence of the entire insert of clone 2.7 is set out in SEQ ID NO: 24.

Attempts to isolate the full length canine α_{TM1} cDNA from the Stratagene library (as described in Example 2) were unsuccessful. Approximately 1 x 10^6 phage plaques were screened by hybridization under low stringency

10   conditions using 30% formamide with clone 2.7 as a probe, but no positive clones resulted. Attempts to amplify relevant sequences downstream from those represented in clone 2.7 using specific oligonucleotides derived from clone 2.7 or degenerate primers based on amino acid sequence from other peptide fragments paired with a degenerate oligonucleotide based on the conserved α subunit amino

15   acid motif GFFKR [Tamura, et al., supra] were also unsuccessful.

                              Example 5
Cloning Of A Putative Human Homolog Of Canine α_{TM1}

To attempt the isolation of a human sequence homologous to canine α_{TM1} the approximately 1 kb canine α_{TM1} fragment from clone 2.7 was used as

20   a probe. The probe was generated by PCR under conditions described in Example 2 using NT2 (as set out in SEQ ID NO: 25) and p4(R) (SEQ ID NO: 23) primers.

5´-GTNTTYCARGARGAYGG-3´   (SEQ ID NO: 25)

The PCR product was purified using the Qiagen (Chatsworth, GA) Quick Spin kit

25   and the manufacturer's suggested protocol. The purified DNA (200 ng) was labeled with 200 μCi α^{32}PdCTP using the Boehringer Mannheim Random Prime

- 25 -

Labelling kit and the manufacturer's suggested protocol. Unincorporated isotope was removed with Sephadex G25 (fine) gravity chromatography. The probe was denatured with 0.2 N NaOH and neutralized with 0.4 M Tris-HCl, pH 8.0, before use.

5   Colony lifts on Hybond filters (Amersham) of a human spleen cDNA library in pCDNA/Amp (Invitrogen, San Diego, CA) were prepared. The filters were initially denatured and neutralized as described in Example 2 and subsequently incubated in a prehybridization solution (8 ml/filter) with 30% formamide at 50°C with gentle agitation for 2 hours. Labeled probe as described

10   above was added to this solution and incubated with the filters for 14 hours at 42°C. The filters were washed twice in 2X SSC/0.1% SDS at 37°C and twice in 2X SSC/0.1% SDS at 50°C. Final stringency washes were 1X SSC/0.1% SDS, twice at 65°C (1X SSC is 150 mM NaCl, 15 mM sodium citrate, pH 7.0). Filters were exposed to Kodak X-Omat AR film for six hours with an intensifying

15   screen. Colonies giving signals on duplicate lifts were streaked on LB medium with magnesium (LBM)/carbenicillin plates and incubated overnight at 37°C. Resulting streaked colonies were lifted with Hybond filters and these filters were treated as above. The filters were hybridized under more stringent conditions with the 1 kb probe from clone 2.7, labeled as previously described, in a 50%

20   formamide hybridization solution at 50°C for 3 hours. Probed filters were washed with a final stringency of 0.1 X SSC/0.1% SDS at 65°C and exposed to Kodak X-Omat AR film for 2.5 hours at -80°C with an intensifying screen. Positive colonies were identified and cultured in LBM/carbenicillin medium overnight. DNA from the cultures was prepared using the Promega Wizard

25   miniprep kit according to the manufacturer's suggested protocol and the resulting DNA was sequenced.

The initial screening resulted in 18 positive clones, while the secondary screening under more stringent hybridization conditions produced one positive clone which was designated 19A2. The DNA and deduced amino acid

- 26 -

sequences of the human α_d clone 19A2 are set out in SEQ ID NOS: 1 and 2, respectively.

Characteristics Of The Human α_d cDNA and Predicted Polypeptide

Clone 19A2 encompasses the entire coding region for the mature
5   protein, plus 48 bases (16 amino acid residues) of the 5´ upstream signal sequence and 241 bases of 3´ untranslated sequence which do not terminate in a polyadenylation sequence. The core molecular weight of the mature protein is predicted to be around 125 kD. The extracellular domain is predicted to encompass approximately amino acid residues 17 through 1108 of SEQ ID NO:
10   2. This extracellular region is contiguous with about a 20 amino acid region homologous to the human CD11c transmembrane region (residues 1109 through 1128 of SEQ ID NO: 2). The cytoplasmic domain comprises approximately 30 amino acids (about residues 1129 through 1161 of SEQ ID NO: 2). The protein also contains a region (around residues 150 through 352) of approximately 202
15   amino acids homologous to the I (insertion) domain common to CD11a, CD11b and CD11c [Larson and Springer, supra], α_E [Shaw, et al., J.Biol.Chem. 269:6016-6025 (1994)] and in VLA-1 and VLA-2, [Tamura, et al., supra]. The I domain in other integrins has been shown to participate in ICAM binding [Landis, et al., J.Cell.Biol. 120:1519-1527 (1993); Diamond, et al., J.Cell.Biol.
20   120:1031-1043 (1993)], suggesting that α_d may also bind members of the ICAM family of surface molecules. This region has not been demonstrated to exist in any other integrin subunits.

The deduced amino acid sequence of α_d shows approximately 36% identity to that of CD11a, approximately 60% identity to CD11b and
25   approximately 66% identity to CD11c. An alignment of amino acid sequences for (CD11b SEQ ID NO: 3), CD11c (SEQ ID NO: 4) and α_d (SEQ ID NO: 2) is presented in Figure 1.

- 27 -

      The cytoplasmic domains of α subunits in β_2 integrins are typically distinct from one another within the same species, while individual α subunits show high degrees of homology across species boundaries. Consistent with these observations, the cytoplasmic region of α_d differs markedly from CD11a, CD11b,

5   and CD11c except for a membrane proximal GFFKR amino acid sequence which has been shown to be conserved among all α integrins [Rojiani, *et al.*, *Biochemistry 30*: 9859-9866 (1991)]. Since the cytoplasmic tail region of integrins has been implicated in "inside out" signaling and in avidity regulation [Landis *et al., supra*], it is possible that α_d interacts with cytosolic molecules distinct from

10   those interacting with CD11a, CD11b, and CD11c, and, as a result, participates in signaling pathways distinct from those involving other β_2 integrins.

      The extracellular domain of α_d contains a conserved DGSGS amino acid sequence adjacent the I-domain; in CD11b, the DGSGS sequence is a metal-binding region required for ligand interaction [Michishita, *et al. Cell*

15   72:857-867 (1993)]. Three additional putative cation binding sites in CD11b and CD11c are conserved in the α_d sequence at amino acids 465-474, 518-527, and 592-600 in clone 19A2 (SEQ ID NO: 1). The α_d I-domain is 36%, 62%, and 57% identical to the corresponding regions in CD11a, CD11b, and CD11c, respectively, and the relatively low sequence homology in this region suggests that

20   α_d may interact with a set of extracellular proteins distinct from proteins with which other known β_2 integrins interact. Alternatively, the affinity of α_d for known β_2 integrin ligands, for example, ICAM-1, ICAM-2 and/or ICAM-R, may be distinct from that demonstrated for the other β_2 integrin/ICAM interactions. [See Example 12.]

- 28 -

Example 6

Northern Analysis of Human α_d Expression in Tissues

In order to determine the relative level of expression and tissue specificity of α_d, Northern analysis was performed using fragments from clone

5   19A2 as probes. Approximately 10 μg of total RNA from each of several human tissues or cultured cell lines were loaded on a formaldehyde agarose gel in the presence of 1 μg of ethidium bromide. After electrophoresis at 100 V for 4 hr, the RNA was transferred to a nitrocellulose membrane (Schleicher & Schuell) by wicking in 10X SSC overnight. The membrane was baked 1.5 hr at 80°C under

10   vacuum.   Prehybridization solution containing 50% formamide in 3-(N-morpholino)propane sulfonic acid (MOPS) buffer was used to block the membrane for 3 hr at 42°C. Fragments of clone 19A2 were labeled with the Boehringer Mannheim Random Prime kit according to the manufacturer's instructions including both αP^{32}dCTP and αP^{32}dTTP. Unincorporated label was removed on

15   a Sephadex G25 column in TE buffer. The membrane was probed with 1.5 x 10⁶ counts per ml of prehybridization buffer. The blot was then washed successively with 2X SSC/0.1% SDS at room temperature, 2X SSC/0.1% SDS at 42°C, 2X SSC/0.1% SDS at 50°C, 1X SSC/0.1% SDS at 50°C, 0.5X SSC/0.1% SDS at 50°C and 0.1X SSC/0.1% SDS at 50°C. The blot was then exposed to film for

20   19 hr.

Hybridization using a BstXI fragment from clone 19A2 (corresponding to nucleotides 2011 to 3388 in SEQ ID NO: 1) revealed a weak signal in the approximately 5 kb range in liver, placenta, thymus, and tonsil total RNA. No signal was detected in kidney, brain or heart samples. The amount of

25   RNA present in the kidney lane was minimal, as determined with ethidium bromide staining.

When using a second fragment of clone 19A2 (encompassing the region from bases 500 to 2100 in SEQ ID NO: 1), RNA transcripts of two different sizes were detected in a human multi-tissue Northern (MTN) blot using

- 29 -

polyA$^+$ RNA (Clontech). An approximately 6.5 kb band was observed in spleen and skeletal muscle, while a 4.5 kb band was detected in lung and peripheral blood leukocytes. The variation in sizes observed could be caused by tissue specific polyadenylation, cross reactivity of the probe with other integrin family members, or hybridization with alternatively spliced mRNAs.

Northern analysis using a third fragment from clone 19A2, spanning nucleotides 2000 to 3100 in SEQ ID NO: 1, gave results consistent with those using the other clone 19A2 fragments.

RNA from three myeloid lineage cell lines was also probed using the fragments corresponding to nucleotides 500 to 2100 and 2000 to 3100 in SEQ ID NO:1. A THP-1 cell line, previously stimulated with PMA, gave a diffuse signal in the same size range (approximately 5.0 kb), with a slightly stronger intensity than the tissue signals. RNA from unstimulated and DMSO-stimulated HL-60 cells hybridized with the α_d probe at the same intensity as the tissue samples, however, PMA treatment seemed to increase the signal intensity. Since PMA and DMSO drive HL-60 cell differentiation toward monocyte/macrophage and granulocyte pathways, respectively, this result suggests enhanced α_d expression in monocyte/macrophage cell types. U937 cells expressed the α_d message and this signal did not increase with PMA stimulation. No band was detected in Molt, Daudi, H9, JY, or Jurkat cells.

Example 7

Transient Expression of Human α_d Constructs

A. Generation of expression constructs

The human clone 19A2 lacks an initiating methionine codon and possibly some of the 5´ signal sequence. Therefore, in order to generate a human expression plasmid containing 19A2 sequences, two different strategies were used. In the first, two plasmids were constructed in which signal peptide sequences derived from genes encoding either CD11b or CD11c were spliced into clone

- 30 -

19A2 to generate a chimeric α_d sequence. In the second approach, a third plasmid was constructed in which an adenosine base was added at position 0 in clone 19A2 to encode an initiating methionine.

5   The three plasmids contained different regions which encoded the 5´ portion of the α_d sequence or the chimeric α_d sequence. The α_d region was PCR amplified (see conditions in Example 2) with a specific 3´ primer BamRev (set out below in SEQ ID NO: 26) and one of three 5´ primers. The three 5´ primers contained in sequence: (1) identical nonspecific bases at positions 1-6 allowing for digestion, an EcoRI site from positions 7-12 and a consensus Kozak

10   sequence from positions 13-18; (2) a portion of the CD11b (primer ER1B) or CD11c (primer ER1C) signal sequence, or an adenosine (primer ER1D); and (3) an additional 15-17 bases specifically overlapping 5´ sequences from clone 19A2 to allow primer annealing. Primers ER1B, ER1C or ER1D are set out in SEQ ID NOS: 27, 28 or 29, respectively, where the initiating methionine codon is

15   underlined and the EcoRI site is double underlined.

5´-CCACTGTCAGGATGCCCGTG-3´   (SEQ ID NO: 26)

5´-AGTTAC<u><u>GAATTC</u></u>GCCACC<u>ATG</u>GCTCTACGGGTGCTT(SEQ ID NO: 27)

20   5´-AGTTAC<u><u>GAATTC</u></u>GCCACC<u>ATG</u>ACTCGGACTGTGCTT(SEQ ID NO: 28)

5´-AGTTAC<u><u>GAATTC</u></u>GCCACC<u>ATG</u>ACCTTCGGCACTGTG(SEQ ID NO: 29)

The resulting PCR product was digested with EcoRI and BamHI.

       All three plasmids contained a common second α_d region (to be

25   inserted immediately downstream from the 5´ region described in the previous paragraph) including the 3´ end of the α_d clone. The second α_d region, which

- 31 -

extended from nucleotide 625 into the *XbaI* site in the vector 3′ polylinker region of clone 19A2, was isolated by digestion of clone 19A2 with *BamHI* and *XbaI*.

Three ligation reactions were prepared in which the 3′ α_d *BamHI/XbaI* fragment was ligated to one of the three 5′ α_d *EcoRI/BamHI* fragments using Boehringer Mannheim ligase buffer and T4 ligase (1 unit per reaction). After a 4 hour incubation at 14°C, an appropriate amount of vector pcDNA.3 (Invitrogen) digested with *EcoRI* and *XbaI* was added to each reaction with an additional unit of ligase. Reactions were allowed to continue for another 14 hours. One tenth of the reaction mixture was then transformed into competent XL-1 Blue cells. The resulting colonies were cultured and the DNA isolated as in Example 5. Digestion with *EcoRI* identified three clones which were positive for that restriction site, and thus, the engineered signal sequences. The clones were designated pATM.B1 (CD11b/α_d, from primer ER1B), pATM.C10 (CD11c/α_d, from primer ER1C) and pATM.D12 (adenosine/α_d from primer ER1d). The presence of the appropriate signal sequences in each clone was verified by nucleic acid sequencing.

B. Transfection of COS Cells

Expression from the α_d plasmids discussed above was effected by cotransfection of COS cells with the individual plasmids and a CD18 expression plasmid, pRC.CD18. As a positive control, COS cells were also co-transfected with the plasmid pRC.CD18 and a CD11a expression plasmid, pDC.CD11A.

Cells were passaged in culture medium (DMEM/10%FBS/pen-strep) into 10 cm Corning tissue culture-treated petri dishes at 50% confluency 16 hours prior to transfection. Cells were removed from the plates with Versene buffer (0.5 mM NaEDTA in PBS) without trypsin for all procedures. Before transfection, the plates were washed once with serum-free DMEM. Fifteen micrograms of each plasmid were added to 5 ml transfection buffer (DMEM with 20 μg/ml DEAE-Dextran and 0.5 mM chloroquine) on each plate. After 1.5

- 32 -

hours incubation at 37°C, the cells were shocked for 1 minute with 5 ml DMEM/10% DMSO. This DMSO solution was then replaced with 10 ml/plate culture medium.

Resulting transfectants were analyzed by ELISA, FACS, and
5   immunoprecipitation as described in Examples 8, 9, and 10.

Example 8

ELISA Analysis of COS Transfectants

In order to determine if the COS cells co-transfected with CD18 expression plasmid pRC.CD18 and an α_d plasmid expressed α_d on the cell surface
10   in association with CD18, ELISAs were performed using primary antibodies raised against CD18 (e.g., TS1/18 purified from ATCC HB203). As a positive control, ELISAs were also performed on cells co-transfected with the CD18 expression plasmid and a CD11a expression plasmid, pDC.CD11A. The primary antibodies in this control included CD18 antibodies and anti-CD11a antibodies
15   (e.g., TS1/22 purified from ATCC HB202).

For ELISA, cells from each plate were removed with Versene buffer and transferred to a single 96-well flat-bottomed Corning tissue culture plate. Cells were allowed to incubate in culture media 2 days prior to assay. The plates were then washed twice with 150 μl/well D-PBS/0.5% teleost skin gelatin
20   (Sigma) solution. This buffer was used in all steps except during the development. All washes and incubations were performed at room temperature. The wells were blocked with gelatin solution for 1 hour. Primary antibodies were diluted to 10 μg/ml in gelatin solution and 50 μl were then added to each well. Triplicate wells were set up for each primary antibody. After 1 hour incubation,
25   plates were washed 3X with 150 μl/well gelatin solution. Secondary antibody (goat anti-mouse Ig/HRP-Fc specific [Jackson, West Grove, PA]) at a 1:3500 dilution was added at 50 μl/well and plates were incubated for 1 hour. After three washes, plates were developed for 20 minutes with 100 μl/well o-

- 33 -

phenyldiamine (OPD) (Sigma) solution (1 mg/ml OPD in citrate buffer) before addition of 50 μl/well 15% sulfuric acid.

Analysis of transfectants in the ELISA format with anti-CD18 specific antibodies revealed no significant expression above background in cells transfected only with the plasmid encoding CD18. Cells co-transfected with plasmid containing CD11a and CD18 showed an increase in expression over background when analyzed with CD18 specific antibodies or with reagents specific for CD11a. Further analysis of cells co-transfected with plasmids encoding CD18 and one of the α_d expression constructs (pATM.C10 or pATM.D12) revealed that cell surface expression of CD18 was rescued by concomitant expression of α_d. The increase in detectable CD18 expression in COS cells transfected with pATM.C10 or pATM.D12 was comparable to that observed in co-transfected CD11a/CD18 positive control cells.

Example 9

FACS Analysis of COS Transfectants

For FACS analysis, cells in petri dishes were fed with fresh culture medium the day after transfection and allowed to incubate 2 days prior to the assay. Transfectant cells were removed from the plates with 3 ml Versene, washed once with 5 ml FACS buffer (DMEM/2% FBS/0.2% sodium azide) and diluted to 500,000 cells/sample in 0.1 ml FACS buffer. Ten microliters of either 1 mg/ml FITC-conjugated CD18, CD11a, or CD11b specific antibodies (Becton Dickinson) or 800 μg/ml CFSE-conjugated murine 23F2G (anti-CD18) (ATCC HB11081) were added to each sample. Samples were then incubated on ice for 45 minutes, washed 3X with 5 ml/wash FACS buffer and resuspended in 0.2 ml FACS buffer. Samples were processed on a Becton Dickinson FACscan and the data analyzed using Lysys II software (Becton Dickinson).

COS cells transfected with CD18 sequences only did not stain for CD18, CD11a or CD11b. When co-transfected with CD11a/CD18, about 15%

of the cells stained with antibodies to CD11a or CD18. All cells transfected with
CD18 and any α_d construct resulted in no detectable staining for CD11a and
CD11b. The pATM.B1, pATM.C10 and pATM.D12 groups stained 4%, 13%
and 8% positive for CD18, respectively. Fluorescence of the positive population

5   in the CD11a/CD18 group was 4-fold higher than background. In comparison,
the co-transfection of α_d constructs with the CD18 construct produced a positive
population that showed a 4- to 7-fold increase in fluorescence intensity over
background.

Example 10

10   Biotin-Labeled Immunoprecipitation of
Human α_d/CD18 Complexes from Co-transfected COS Cells

Immunoprecipitation was attempted on cells co-transfected with
CD18 and each of the α_d expression plasmids separately described in Example 7
in order to determine if α_d could be isolated as part of the $\alpha\beta$ heterodimer

15   complex characteristic of integrins.

Transfected cells (1-3 x 10^8 cells/group) were removed from petri
dishes with Versene buffer and washed 3 times in 50 ml/group D-PBS. Each
sample was labeled with 2 mg Sulpho-NHS Biotin (Pierce, Rockford, IL) for 15
minutes at room temperature. The reaction was quenched by washing 3 times in

20   50 ml/sample cold D-PBS. Washed cells were resuspended in 1 ml lysis buffer
(1% NP40, 50 mM Tris-HCl, pH 8.0, 0.2 M NaCl, 2 mM Ca^{++}, 2 mM Mg^{++},
and protease inhibitors) and incubated 15 minutes on ice. Insoluble material was
pelleted by centrifugation at 10,000 g for 5 minutes, and the supernatant removed
to fresh tubes. In order to remove material non-specifically reactive with mouse

25   immunoglobulin, a pre-clearance step was initially performed. Twenty-five
micrograms of mouse immunoglobulin (Cappel, West Chester, PA) was incubated
with supernatants at 4°C. After 2.5 hr, 100 μl (25 μg) rabbit anti-mouse Ig
conjugated Sepharose (prepared from Protein A Sepharose 4B and rabbit anti-
mouse IgG, both from Zymed, San Francisco, CA) was added to each sample;

- 35 -

incubation was continued at 4°C with rocking for 16 hours. Sepharose beads were removed from the supernatants by centrifugation. After pre-clearance, the supernatants were then treated with 20 μg anti-CD18 antibody (TS1.18) for 2 hours at 4°C. Antibody/antigen complexes were isolated from supernatants by incubation with 100 μl/sample rabbit anti-mouse/Protein A-sepharose preparation described above. Beads were washed 4 times with 10 mM HEPES, 0.2 M NaCl, and 1% Triton-X 100. Washed beads were pelleted and boiled for 10 minutes in 20 μl 2X Laemmli sample buffer with 2% β-mercaptoethanol. Samples were centrifuged and run on an 8% prepoured Novex polyacrylamide gel (Novex) at 100 V for 30 minutes. Protein was transferred to nitrocellulose membranes (Schleicher & Schuell) in TBS-T buffer at 200 mAmps for 1 hour. Membranes were blocked for 2 hr with 3% BSA in TBS-T. Membranes were treated with 1:6000 dilution of Strep-avidin horse radish peroxidase (POD) (Boehringer Mannheim) for 1 hour, followed by 3 washes in TBS-T. The Amersham Enhanced Chemiluminescence kit was then used according to the manufacturer's instructions to develop the blot. The membrane was exposed to Hyperfilm MP (Amersham) for 0.5 to 2 minutes.

Immunoprecipitation of CD18 complexes from cells transfected with pRC.CD18 and either pATM.B1, pATM.C10 or pATM.D12 revealed surface expression of a heterodimeric species consisting of approximately 100 kD β chain, consistent with the predicted size of CD18, and an α chain of approximately 150 kD, corresponding to α_d.

Example 11

Stable Transfection of Human α_d in Chinese Hamster Ovary Cells

To determine whether α_d is expressed on the cell surface as a heterodimer in association with CD18, cDNAs encoding each chain were both transiently and stably transfected into a cell line lacking both α_d and CD18.

- 36 -

For these experiments, α_d cDNA was augmented with additional leader sequences and a Kozak consensus sequence, as described in Example 7, and subcloned into expression vector pcDNA3. The final construct, designated pATM.D12, was co-transfected with a modified commercial vector, pDC1.CD18

5   encoding human CD18 into dihydrofolate reductase (DHFR)⁻ Chinese hamster ovary (CHO) cells. The plasmid pDC1.CD18 encodes a DHFR⁺ marker and transfectants can be selected using an appropriate nucleoside-deficient medium. The modifications which resulted in pDC1.CD18 are as follows.

The plasmid pRC/CMV (Invitrogen) is a mammalian expression

10   vector with a cytomegalovirus promoter and ampicillin resistance marker gene. A DHFR gene from the plasmid pSC1190-DHFR was inserted into pRC/CMV 5´ of the SV40 origin of replication. In addition, a polylinker from the 5´ region of the plasmid pHF2G-DHF was ligated into the pRC/CMV/DHFR construct, 3´ to the DHFR gene. CD18 encoding sequences are subsequently cloned into the

15   resulting plasmid between the 5´ flanking polylinker region and the bovine growth hormone poly A encoding region.

Surface expression of CD18 was analyzed by flow cytometry using the monoclonal antibody TS1/18. Heterodimer formation detected between α_d and CD18 in this cell line was consistent with the immunoprecipitation described

20   in Example 10 with transient expression in COS cells.

Example 12

Human α_d binds to ICAM-R in a CD18-dependent fashion

In view of reports that demonstrate interactions between the leukocyte integrins and intercellular adhesion molecules (ICAMs) which mediate

25   cell-cell contact [Hynes, *Cell* 69:11-25 (1992)], the ability of CHO cells expressing α_d/CD18 to bind ICAM-1, ICAM-R, or VCAM-1 was assessed by two methods.

- 37 -

In replicate assays, soluble ICAM-1, ICAM-R, or VCAM-1 IgG1 fusion proteins were immobilized on plastic and the ability of α_d/CD18 CHO transfected cells to bind the immobilized ligand was determined. Transfected cells were labeled internally with calcein, washed in binding buffer (RPMI with 1%

5   BSA), and incubated in either buffer only (with or without 10 ng/ml PMA) or buffer with anti-CD18 monoclonal antibodies at 10 μg/ml. Transfected cells were added to 96-well Immulon 4 microtiter plates previously coated with soluble ICAM-1/IgG1, ICAM-R/IgG1 or VCAM-1/IgG1 fusion protein, or bovine serum albumin (BSA) as a negative control. Design of the soluble forms of these

10   adhesion molecules is described and fully disclosed in co-pending and co-owned U.S. Patent Application Serial No. 08/102,852, filed August 5, 1993. Wells were blocked with 1% BSA in PBS prior to addition of labeled cells. After washing the plates by immersion in PBS with 0.1% BSA for 20 minutes, total fluorescence remaining in each well was measured using a Cytofluor 2300 (Millipore, Milford,

15   MA).

In experiments with immobilized ICAMs, α_d/CD18 co-transfectants consistently showed a 3-5 fold increase in binding to ICAM-R/IgG1 wells over BSA coated wells. The specificity and CD18-dependence of this binding was demonstrated by the inhibitory effects of anti-CD18 antibody TS1/18. The binding

20   of cells transfected with CD11a/CD18 to ICAM-1/IgG1 wells was comparable to the binding observed with BSA coated wells. CD11a/CD18 transfected cells showed a 2-3 fold increase in binding to ICAM-1/IgG1 wells only following pretreatment with PMA. PMA treatment of α_d/CD18 transfectants did not affect binding to ICAM-1/IgG1 or ICAM-R/IgG1 wells. No detectable binding of

25   α_d/CD18 transfectants to VCAM-1/IgG1 wells was observed.

Binding of α_d/CD18-transfected cells to soluble ICAM-1/IgG1, ICAM-R/IgG1, or VCAM-1/IgG1 fusion proteins was determined by flow cytometry. Approximately one million α_d/CD18-transfected CHO cells (grown in spinner flasks for higher expression) per measurement were suspended in 100 μl

- 38 -

binding buffer (RPMI and 1% BSA) with or without 10 μg/ml anti-CD18 antibody. After a 20 minute incubation at room temperature, the cells were washed in binding buffer and soluble ICAM-1/IgG1 or ICAM-R/IgG1 fusion protein was added to a final concentration of 5 μg/ml. Binding was allowed to

5   proceed for 30 minute at 37°C, after which the cells were washed three times and resuspended in 100 μl binding buffer containing FITC-conjugated sheep anti-human IgG1 at a 1:100 dilution. After a 30 minute incubation, samples were washed three times and suspended in 200 μl binding buffer for analysis with a Becton Dickinson FACScan.

10   Approximately 40-50% of the α_d/CD18 transfectants indicated binding to ICAM-R/IgG1, but no binding to ICAM-1/IgG1 or VCAM-1/IgG1 proteins. Pretreatment of transfected cells with PMA has no effect on α_d/CD18 binding to either ICAM-1/IgG1, ICAM-R/IgG1 or VCAM-1/IgG1, which was consistent with the immobilized adhesion assay. Binding by ICAM-R was

15   reduced to background levels after treatment of α_d/CD18 transfectants with anti-CD18 antibody TS1/18.

The collective data from these two binding assays illustrate that α_d/CD18 binds to ICAM-R and does so preferentially as compared to ICAM-1 and VCAM-1. The α_d/CD18 binding preference for ICAM-R over ICAM-1 is

20   opposite that observed with CD11a/CD18 and CD11b/CD18. Thus modulation of α_d/CD18 binding may be expected to selectively affect normal and pathologic immune function where ICAM-R plays a prominent role. Moreover, results of similar assays, in which antibodies immunospecific for various extracellular domains of ICAM-R were tested for their ability to inhibit binding of ICAM-R

25   to α_d/CD18 transfectants, indicated that α_d/CD18 and CD11a/CD18 interact with different domains of ICAM-R.

The failure of CD11a/CD18 to bind ICAM-1/IgG1 or ICAM-R/IgG1 in solution suggests that the affinity of binding between CD11a/CD18 and ICAM-1 or ICAM-R is too low to permit binding in solution. Detection of

- 39 -

α_d/CD18 binding to ICAM-R/IgG1, however, suggests an unusually high binding affinity.

α_d Binding to iC3b

Complement component C3 can be proteolytically cleaved to form
5   the complex iC3b, which initiates the alternative pathway of complement activation and leads ultimately to cell-mediated destruction of a target. Both CD11b and CD11c have been implicated in iC3b binding and subsequent phagocytosis of iC3b-coated particles. A peptide fragment in the CD11b I domain has recently been identified as the site of iC3b interaction [Ueda, *et al.*,
10   *Proc.Natl.Acad.Sci. (USA) 91*:10680-10684 (1994)]. The region of iC3b binding is highly conserved in CD11b, CD11c, and α_d, suggesting an α_d/iC3b binding interaction.

Binding of α_d to iC3b is performed using transfectants or cell lines naturally expressing α_d (for example, PMA-stimulated HL60 cells) and iC3b-
15   coated sheep red blood cells (sRBC) in a rosette assay [Dana, *et al.*, *J. Clin. Invest.* *73*:153-159 (1984)]. The abilities of α_d/CD18 CHO transfectants, VLA4-CHO transfectants (negative control) and PMA-stimulated HL60 cells (positive control) to form rosettes are compared in the presence and absence of an anti-CD18 monoclonal antibody (for example TS1/18.1).

20   Example 13
Screening by Scintillation Proximity Assay

Specific inhibitors of binding between the α_d ligands of the present invention and their binding partners (α_d ligand/anti-ligand pair) may be determined by a variety of means, such as scintillation proximity assay techniques
25   as generally described in U.S. Patent No. 4,271,139, Hart and Greenwald, *Mol.Immunol. 12*:265-267 (1979), and Hart and Greenwald, *J.Nuc.Med.* *20*:1062-1065 (1979), each of which is incorporated herein by reference.

- 40 -

Briefly, one member of the α_d ligand/anti-ligand pair is bound to
a solid support. A fluorescent agent is also bound to the support. Alternatively,
the fluorescent agent may be integrated into the solid support as described in U.S.
Patent No. 4,568,649, incorporated herein by reference. The non-support bound
5   member of the α_d ligand/anti-ligand pair is labeled with a radioactive compound
that emits radiation capable of exciting the fluorescent agent. When the ligand
binds the radiolabeled anti-ligand, the label is brought sufficiently close to the
support-bound fluorescer to excite the fluorescer and cause emission of light.
When not bound, the label is generally too distant from the solid support to excite
10   the fluorescent agent, and light emissions are low. The emitted light is measured
and correlated with binding between the ligand and the anti-ligand. Addition of
a binding inhibitor to the sample will decrease the fluorescent emission by keeping
the radioactive label from being captured in the proximity of the solid support.
Therefore, binding inhibitors may be identified by their effect on fluorescent
15   emissions from the samples. Potential anti-ligands to α_d may also be identified
by similar means.

Example 14

Soluble Human α_d Expression Constructs

The expression of full-length, soluble human α_d/CD18
20   heterodimeric protein provides easily purified material for immunization and
binding assays. The advantage of generating soluble protein is that it can be
purified from supernatants rather than from cell lysates (as with full-length
membrane-bound α_d/CD18); recovery in therefore improved and impurities
reduced.

25   The soluble α_d expression plasmid was constructed as follows. A
nucleotide fragment corresponding to the region from bases 0 to 3161 in SEQ ID
NO: 1, cloned into plasmid pATM.D12, was isolated by digestion with HindIII
and AatII. A PCR fragment corresponding to bases 3130 to 3390 in SEQ ID NO:

- 41 -

1, overlapping the *Hind*III/*Aat*II fragment and containing an addition *Mlu*I restriction site at the 3´ terminus, was amplified from pATM.D12 with primers sHAD.5 and sHAD.3 set out in SEQ ID NOS: 30 and 31, respectively.

5´-TTGCTGACTGCCTGCAGTTC-3´   (SEQ ID NO: 30)

5´-GTTCTGACGCGTAATGGCATTGTAGACCTCGTCTTC(SEQ ID NO: 31)

The PCR amplification product was digested with *Aat*II and *Mlu*I and ligated to the *Hind*III/*Aat*II fragment. The resulting product was ligated into *Hind*III/*Mlu*I-digested plasmid pDC1.s.

This construct is co-expressed with soluble CD18 in stably transfected CHO cells, and expression is detected by autoradiographic visualization of immunoprecipitated CD18 complexes derived from ^{35}S-methionine labeled cells. The construct is also co-expressed with CD18 in 293 cells [Berman, et al., *J.Cell.Biochem.* 52:183-195 (1993)].

Soluble Human α_d I Domain Expression Constructs

It has previously been reported that the I domain in CD11a can be expressed as an independent structural unit that maintains ligand binding capabilities and antibody recognition [Randi and Hogg, *J.Biol.Chem.* 269:12395-12398 (1994); Zhout, et al., *J.Biol.Chem.* 269:17075-17079 (1994); Michishita, et al., *Cell* 72:857-867 (1993)]. To generate a soluble fusion protein comprising the α_d I domain and human IgG4, the α_d I domain is amplified by PCR using primers designed to add flanking *Bam*HI and *Xho*I restriction sites to facilitate subcloning. These primers are set out in SEQ ID NOS: 32 and 33 with restriction sites underlined.

5´-ACGTATGCA<u>GGATCC</u>CATCAAGAGATGGACATCGC(SEQ ID NO: 32)

5´-ACTGCATGT<u>CTCGAG</u>GCTGAAGCCTTCTTGGGACAT(SEQ ID NO: 33)

- 42 -

The C nucleotide immediately 3´ to the *Bam*HI site in SEQ ID NO: 32 corresponds to nucleotide 435 in SEQ ID NO: 1; the G nucleotide 3´ to the *Xho*I site in SEQ ID NO: 33 is complementary to nucleotide 1067 in SEQ ID NO: 1. The amplified I domain is digested with the appropriate enzymes, the purified fragment ligated into the mammalian expression vector pDCs and the prokaryotic expression vector pGEX-4T-3 (Pharmacia) and the I domain fragment sequenced. The fusion protein is then expressed in COS, CHO or *E.coli* cells transfected or transformed with an appropriate expression construct.

Given the affinity of α_d for ICAM-R, expression of the α_d I domain may be of sufficient affinity to be a useful inhibitor of cell adhesion in which α_d participates.

Analysis of Human α_d I Domain/IgG4 Fusion Proteins

Protein was resolved by SDS-PAGE under reducing and non-reducing conditions and visualized by either silver staining or Coomassie staining. Protein was then transferred to Immobilon PVDF membranes and subjected to Western blot analysis using anti-human IgG monoclonal antibodies or anti-bovine Ig monoclonal antibodies.

Protein detected was determined to migrate at about 120 kD under non-reducing conditions and at about 45 kD under reducing conditions. Minor bands were also detected on non-reducing gels at approximately 40-50 kD which were reactive with the anti-human, but not anti-bovine, antibodies. A 200 kD minor band was determined to be bovine Ig by Western blot.

Binding Assays Using I Domain Expression Products

The ability of the I domain to specifically recognize ICAM-R/IgG chimeric protein was tested in an ELISA format. Serial dilutions of α_d I domain IgG4 fusion protein (Iα_d/IgG4) in TBS were incubated with ICAM-1/IgG, ICAM-R/IgG, VCAM-1/IgG, or an irrelevant IgG1 myeloma protein

- 43 -

immobilized on Immulon IV RIA/EIA plates. CD11a I domain/IgG chimeric protein and human IgG4/kappa myeloma protein were used as negative controls. Bound IgG4 was detected with the biotinylated anti-IgG4 monoclonal antibody HP6023 followed by addition of strepavidin-peroxidase conjugate and development

5   with substrate o-phenyldiamine.

In repeated assays, no binding of the CD11a/IgG4 protein or the IgG4 myeloma protein was detected with any of the immobilized proteins. The Iα_d/IgG4 protein did not bind to fish skin gelatin or bovine serum albumin blocking agents, human IgG1, or ICAM-1/IgG. A two to three fold increase in

10   binding signal over background was detected in ICAM-R/IgG protein coated wells using 1-5 μg/ml concentrations of Iα_d/IgG4 protein. The signal in VCAM-1/IgG protein coated wells was 7-10 fold higher than background. In previous assays, α_d/CD18 transfected CHO cells did not bind VCAM-1/IgG protein, suggesting that VCAM-1 binding may be characteristic of isolated I domain amino acid

15   sequences.

Additional α_d I domain constructs

Additional α_d I domain constructs are generated in the same fashion as the previous construct, but incorporating more amino acids around the α_d I domain. Specific constructs include: i) sequences from exon 5 (amino acids 127-

20   353 in SEQ ID NO: 2), preceding the current construct, ii) the EF-hand repeats (amino acids 17-603 in SEQ ID NO: 2) following the I domain, and iii) the alpha chain truncated at the transmembrane region (amino acids 17-1029 in SEQ ID NO: 2), with an IgG4 tail for purification and detection purposes. These constructs are ligated into either the mammalian expression vector pDCS1 or the

25   prokaryotic expression vector pGEX-4T-3 (Pharmacia) and the I domain sequenced. The fusion proteins are then be expressed in COS, CHO, or E.coli cells transformed or transfected with an appropriate expression construct. Protein are purified on a ProSepA column (Bioprocessing Limited, Durham, England),

- 44 -

tested for reactivity with the anti-IgG4 monoclonal antibody HP6023 and visualized on polyacrylamide gels with Coomassie staining.

In order to construct an expression plasmid for the entire α_d polypeptide, pATM.D12, described *supra*, is modified to express an α_d-IgG4

5   fusion protein by the following method. IgG4 encoding DNA is isolated from the vector pDCS1 by PCR using primers which individually incorporate a 5′ *Aat*II restriction site (SEQ ID NO: 89) and a 3′ *Xba*1 restriction site (SEQ ID NO: 90).

5′-CGCTGTGACGTCAGAGTTGAGTCCAAATATGG-3′   (SEQ ID NO: 89)

5′-GGTGACACTATAGAATAGGGC-3′   (SEQ ID NO: 90)

10   Plasmid pATM.D12 is digested with *Aat*II and *Xba*1, and the appropriately digested and purified IgG4 PCR product ligated into the linear vector.

- 45 -

Example 15

Production of Human α_d-Specific Monoclonal Antibodies

       Transiently transfected cells from Example 7 were washed three times in Dulbecco's phosphate buffered saline (D-PBS) and injected at 5×10^6

5   cells/mouse into Balb/c mice with 50 μg/mouse muramyl dipeptidase (Sigma) in PBS. Mice were injected two more times in the same fashion at two week intervals. The pre-bleed and immunized serum from the mice were screened by FACS analysis as outlined in Example 9 and the spleen from the mouse with the highest reactivity to cells transfected with α_d/CD18 was fused. Hybridoma

10   culture supernatants were then screened separately for lack of reactivity against COS cells transfected with CD11a/CD18 and for reactivity with cells co-transfected with an α_d expression plasmid and CD18.

       This method resulted in no monoclonal antibodies.

       As an alternative for production of monoclonal antibodies, soluble

15   α_d I domain IgG4 fusion protein was affinity purified from supernatant of stably transfected CHO cells and used to immunize Balb/c mice as described above. Hybridomas were established and supernatants from these hybridomas were screened by ELISA for reactivity against α_d I domain fusion protein. Positive cultures were then analyzed for reactivity with full length α_d/CD18 complexes

20   expressed on CHO transfectants.

       Mouse 1908 received three initial immunizations of α_d/CD18 transfected CHO cells and two subsequent boosts with soluble α_d/CD18 heterodimer. Two final immunizations included 50 μg/mouse Iα_d/IgG4 fusion protein. The fusion produced 270 IgG-producing wells. Supernatant from 45

25   wells showed at least 7-fold higher binding to Iα_d/IgG4 fusion protein than to human IgG4 by ELISA. None of the supernatants reacted to α_d/CD18 transfected CHO cells as determined by FACS analysis.

       To determine whether the supernatants were able to recognize integrin alpha subunit proteins in another context, fresh frozen splenic sections

- 46 -

were stained with supernatants from 24 of the 45 wells. Three supernatants were determined to be positive: one stained large cells in the red pulp, while two others stained scattered cells in the red pulp and also trabeculae.

5   These supernatants were further analyzed by their ability to immunoprecipitate biotinylated CD18 complexes from either α_d/CD18 transfected CHO cells or PMA-stimulated HL60 cells. Fusion wells with supernatants that recognized protein in detergent lysates (which should not be as conformationally constrained as protein expressed as heterodimers) were selected for further subcloning. Monoclonal antibodies which recognize protein in detergent may be 10   more useful in immunoprecipitation of heterodimeric complexes from transfectants, tissues, and cell lines.

As another alternative, monoclonal antibodies are generated as follows. Affinity purified α_d/CD18 heterodimeric protein from detergent lysates of stably transfected CHO cells is used with 50 μg/ml muramyl dipeptidase to 15   immunize Balb/c mice as described above. Mice receive three immunizations before serum reactivity against α_d/CD18 is determined by immunoprecipitation of biotinylated complexes in the CHO transfectants. Hybridomas from positive animals are established according to standard protocols, after which hybridoma cultures are selected by flow cytometry using α_d/CD18 transfectants. 20   CD11a/CD18 transfectants are utilized to control for CD18-only reactivity.

As another alternative for monoclonal antibody production, Balb/c mice undergo an immunization/immunosuppression protocol designed to reduce reactivity to CHO cell determinants on transfectants used for immunization. This protocol involves immunization with untransfected CHO cells and subsequent 25   killing of CHO-reactive B-cell blasts with cyclophosphamide treatment. After three rounds of immunization and cyclophosphamide treatment are performed, the mice are immunized with α_d/CD18 CHO transfected cells as described above.

As still another alternative, heterodimeric CD18 complexes are immunoprecipitated from detergent lysates of whole spleen using an anti-CD18

- 47 -

monoclonal antibody, following preclearance of CD11a/CD18 and CD11b/CD18. CD11a/CD18 and CD11b/CD18 complexes are precleared by affinity chromatography using monoclonal antibodies TS2/4 and Mo1, respectively, coupled to a chromatographic resin. The remaining CD18 complexes are used as an immunogen in Balb/c mice for the first immunization. Three immunizations are given at three week intervals, the initial immunization administered in conjunction with Freund's Complete Adjuvant and the subsequent immunizations with Freund's Incomplete Adjuvant. Serum is assayed for α_d-specific reactivity by immunoprecipitation. Resulting hybridomas are screened by flow cytometry with α_d/CD18 CHO transfectants.

As another alternative, CD18 complexes from detergent lysates of PMA stimulated HL60 cells are enriched by preclearance as described above. Other $\beta 2$ integrins are cleared on the same columns. Immunization with the resulting complexes, hybridoma production, and screening protocols are performed as described *supra*.

Example 16

Analysis of α_d distribution with polyclonal serum

Tissue distribution of α_d/CD18 was determined using polyclonal antiserum. Antiserum used to stain tissue was obtained from a mouse immunized 3 times with α_d transfected CHO cells (D6.CHO, α_d/CD18) with adjuvant peptide and once with purified α_d/CD18 heterodimer. A final boost included only α_d/CD18 heterodimer. Approximately 100 μl immunized serum was precleared by addition of approximately 10^8 LFA-1-transfected CHO cells for 2 hours at 4°C. The resulting serum was assayed for α_d reactivity at dilutions of 1/5000, 1/10000, 1/20000 and 1/40000 on normal human spleen. The polyclonal antibody was reactive at a dilution of 1/20000, while a 1/40000 dilution stained very weakly.

- 48 -

Once serum was determined to have specific α_d reactivity, it was used to stain various lymphoid and non-lymphoid tissues. Monoclonal antibodies recognizing CD18, CD11a, CD11b, and CD11c were used in the same experiment as controls. Staining of normal spleen sections with α_d polyclonal

5   sera, and monoclonal antibodies to CD11a, CD11b, CD11c, and CD18 revealed the following results. The pattern observed with α_d polyclonal sera did not display the same pattern of labeling as CD11a, CD11b, CD11c, or CD18. There is a distinct pattern of labeling with some cells located in the marginal zone of the white pulp and a distinct labeling of cells peripheral to the marginal zone. This

10   pattern was not observed with the other antibodies. Individual cells scattered throughout the red pulp were also labeled which may or may not be the same population or subset seen with CD11a and CD18.

Labeling with CD11c did display some cells staining in the marginal zone, but the antibody did not show the distinct ring pattern around the

15   white pulp when compared to α_d polyclonal sera, nor did labeling in the red pulp give the same pattern of staining as α_d polyclonal sera.

Therefore, the labeling pattern seen with α_d polyclonal serum was unique compared to that seen using antibodies to the other β_2 integrins (CD11a, CD11b, CD11c, and CD18), and suggests that the *in vivo* distribution of α_d in

20   man is dinstinct from that of other β_2 integrins.

Example 17

Isolation of Rat cDNA Clones

In view of the existence of both canine and human α_d subunits, attempts were made to isolate homologous genes in other species, including rat

25   (this example) and mouse (Example 17, *infra*).

A partial sequence of a rat cDNA showing homology to the human α_d gene was obtained from a rat splenic λgt10 library (Clontech). The library was plated at 2 x 10^4 pfu/plate onto 150 mm LBM/agar plates. The library was

- 49 -

lifted onto Hybond membranes (Amersham), denatured 3 minutes, neutralized 3 minutes and washed 5 minutes with buffers as described in standard protocols [Sambrook, et al., Molecular Cloning: a laboratory manual, p.2.110]. The membranes were placed immediately into a Stratalinker (Stratagene) and the DNA

5   crosslinked using the autocrosslinking setting. The membranes were prehybridized and hybridized in 30% or 50% formamide, for low and high stringency conditions, respectively. Membranes were initially screened with a ^{32}P-labeled probe generated from the human α_d cDNA, corresponding to bases 500 to 2100 in clone 19A2 (SEQ ID NO: 1). The probe was labeled using

10   Boehringer Mannheim's Random Prime Kit according to manufacturer's suggested protocol. Filters were washed with 2X SSC at 55°C.

Two clones, designated 684.3 and 705.1, were identified which showed sequence homology to human α_d, human CD11b, and human CD11c. Both clones aligned to the human α_d gene in the 3' region of the gene, starting

15   at base 1871 and extending to base 3012 for clone 684.3, and bases 1551 to 3367 for clone 705.1.

In order to isolate a more complete rat sequence which included the 5' region, the same library was rescreened using the same protocol as employed for the initial screening, but using a mouse probe generated from clone A1160

20   (See Example 17, infra). Single, isolated plaques were selected from the second screening and maintained as single clones on LBM/agar plates. Sequencing primers 434FL and 434FR (SEQ ID NOS: 34 and 35, respectively) were used in a standard PCR protocol to generate DNA for sequencing.

5'-TATAGACTGCTGGGTAGTCCCCAC-3'   (SEQ ID NO: 34)

25   5'-TGAAGATTGGGGGTAAATAACAGA-3'   (SEQ ID NO: 35)

DNA from the PCR was purified using a Quick Spin Column (Qiagen) according to manufacturer's suggested protocol.

- 50 -

Two clones, designated 741.4 and 741.11, were identified which overlapped clones 684.3 and 705.1; in the overlapping regions, clones 741.1 and 741.11 were 100% homologous to clones 684.3 and 705.1. A composite rat cDNA having homology to the human α_d gene is set out in SEQ ID NO: 36; the

5   predicted amino acid sequence is set forth in SEQ ID NO: 37.

Cloning of the 5´ end of Rat α_d

A 5´ cDNA fragment for the rat α_d gene was obtained using a Clonetech rat spleen RACE cloning kit according to manufacturer's suggested protocol. The gene specific oligonucleotides used were designated 741.11#2R and

10   741.2#1R (SEQ ID NOS: 59 and 58, respectively).

5´-CCAAAGCTGGCTGCATCCTCTC-3´   (SEQ ID NO: 59)

5´-GGCCTTGCAGCTGGACAATG-3´   (SEQ ID NO: 58)

Oligo 741.11#2R encompasses base pairs 131-152 in SEQ ID NO: 36, in the reverse orientation and 741.2#1R encompasses bases pairs 696-715 in SEQ ID

15   NO: 36, also in the reverse orientation. A primary PCR was carried out using the 3´-most oligo, 741.2#1R. A second PCR followed using oligo 741.11#2R and DNA generated from the primary reaction. A band of approximately 300 base pairs was detected on a 1% agarose gel.

The secondary PCR product was ligated into plasmid pCRTAII

20   (Invitrogen) according to manufacturer's suggested protocol. White (positive) colonies were picked and added to 100 μl LBM containing 1 μl of a 50 mg/ml carbenicillin stock solution and 1 μl M13 K07 phage culture in individual wells in a round bottom 96 well tissue culture plate. The mixture was incubated at 37°C for 30 minutes to one hour. Following the initial incubation period, 100 μl

25   of LBM (containing 1 μl of 50 mg/ml carbenicillin and a 1:250 dilution of a 10

- 51 -

mg/ml kanamycin stock solution) were added and the incubation was continued overnight at 37°C.

Using a sterile 96 well metal transfer prong, supernatant from the 96 well plate was transferred to four Amersham Hybond nylon filters. The filters
5   were denatured, neutralized and cross linked by standard protocols. The filters were prehybridized in 20 mls of prehybridization buffer (5X SSPE; 5X Denhardts; 1% SDS; 50 ugs/ml denatured salmon sperm DNA) at 50°C for several hours while shaking.

Oligo probes 741.11#1 and 741.11#1R (SEQ ID NOS: 56 and 57,
10   respectively), encompassing base pairs 86-105 (SEQ ID NO: 36) in the forward and reverse orientation respectively, were labeled as follows.

5′-CCTGTCATGGGTCTAACCTG-3′   (SEQ ID NO: 56)

5′-AGGTTAGACCCATGACAGG-3′   (SEQ ID NO: 57)

Approximately 65 ng oligo DNA in 12 μl dH$_2$0 was heated to 65°C for two
15   minutes. Three μl of 10 mCi/ml γ-^{32}P-ATP were added to the tube along with 4 μl 5x Kinase Buffer (Gibco) and 1 μl T4 DNA Kinase (Gibco). The mixture was incubated at 37°C for 30 minutes. Following incubation, 16 μl of each labeled oligo probe were added to the prehybridization buffer and filters and hybridization was continued overnight at 42°C. The filters were washed three
20   times in 5X SSPE; 0.1% SDS for 5 minutes per wash at room temperature, and autoradiographed for 6 hours. Positive clones were expanded and DNA purified using the Magic Mini Prep Kit (Promega) according to manufacturer's suggested protocol. Clone 2F7 was selected for sequencing and showed 100% homology ～ clone 741.11 in the overlapping region. The complete rat α_d nucleic acid
25   sequence is set out in SEQ ID NO: 54; the amino acid sequence is set out in SEQ ID NO: 55.

- 52 -

Characteristics of the Rat cDNA and Amino Acid Sequences

Neither nucleic acid nor amino acid sequences have previously been reported for rat α subunits in β_2 integrins. However sequence comparisons to reported human β_2 integrin α subunits suggests that the isolated rat clone and its predicted amino acid sequence are most closely related to α_d nucleotide and amino acid sequences.

At the nucleic acid level, the isolated rat cDNA clone shows 80% identity in comparison to the human α_d cDNA; 68% identity in comparison to human CD11b; 70% identity in comparison to human CD11c; and 65% identity in comparison to mouse CD11b. No significant identity is found in comparison to human CD11a and to mouse CD11a.

At the amino acid level, the predicted rat polypeptide encoded by the isolated cDNA shows 70% identity in comparison to human α_d polypeptide; 28% identity in comparison to human CD11a; 58% identity in comparison to human CD11b; 61% identity in comparison to human CD11c; 28% identity in comparison to mouse CD11a; and 55% identity in comparison to mouse CD11b.

Example 18

Monoclonal Antibodies against Rat α_d I domain/Hu IgG4 Fusion Proteins

In view of the fact that the I domain of human β_2 integrins has been demonstrated to participate in ligand binding, it was assumed that the same would be true for rat α_d protein. Monoclonal antibodies immunospecific for the rat α_d I domain may therefore be useful in rat models of human disease states wherein α_d binding is implicated.

Oligos "rat alpha-DI5" (SEQ ID NO: 87) and "rat alpha-DI3" (SEQ ID NO: 88) were generated from the rat α_d sequence corresponding to base pairs 469-493 and base pairs 1101-1125 (in the reverse orientation), respectively, in SEQ ID NO: 54. The oligos were used in a standard PCR reaction to generate a rat α_d DNA fragment containing the I domain spanning base pairs 459-1125 in

- 53 -

SEQ ID NO: 54. The PCR product was ligated into vector pCRTAII (Invitrogen) according to manufacturer's suggested protocol. A positive colony was selected and expanded for DNA purification using a Qiagen (Chatswoth, GA) Midi Prep kit according to manufacturer's protocol. The DNA was digested with XhoI and

5   BgIII in a standard restriction enzyme digest and a 600 base pair band was gel purified which was subsequently ligated into pDCS1/HuIgG4 expression vector. A positive colony was selected, expanded and DNA purified with a Quiagen Maxi Prep Kit.

        COS cells were plated at half confluence on 100mm culture dishes

10   and grown overnight at 37°C in 7% CO_2. Cells were rinsed once with 5 ml DMEM. To 5 ml DMEM, 50 μl DEAE-Dextran, 2 μl chloroquine and 15 μg rat α_d I domain/HuIgG4 DNA described above was added. The mixture was added to the COS cells and incubated at 37°C for 3 hours. Media was then removed and 5 ml 10% DMSO in CMF-PBS was added for exactly one minute. The cells

15   were gently rinsed once with DMEM. Ten ml DMEM containing 10% FBS was added to the cells and incubation continued overnight at 37°C in 7% CO_2. The next day, media was replaced with fresh media and incubation continued for three additional days. The media was harvested and fresh media was added to the plate. After three days, the media was collected again and the plates discarded.

20   The procedure was repeated until 2 liters of culture supernatant were collected.

        Supernatant collected as described above was loaded onto a Prosep-A column (Bioprocessing Limited) and protein purified as described below.

        The column was initially washed with 15 column volumes of Wash

25   Buffer containing 35 mM Tris and 150 mM NaCl, pH 7.5. Supernatant was loaded at a slow rate of less than approximately 60 column volumes per hour. After loading, the column was washed with 15 column volumes of Wash Buffer, 15 column volumes of 0.55 M diethanolamine, pH 8.5, and 15 column volumes

- 54 -

50 mM citric acid, pH 5.0. Protein was eluted with 50 mM citric acid, pH 3.0. Protein was neutralized with 1.0 M Tris, pH 8.0, and dialyzed in sterile PBS.

The rat α_d I domain protein was analyzed as described in Example 14. The detected protein migrated in the same manner as observed with human

5   I domain protein.

Immunization Protocol

Mice were individually immunized with 50 μg purified rat α_d I domain/HuIgG4 fusion protein previously emulsified in an equal volume of Freunds Complete Adjuvant (FCA) (Sigma). Approximately 200 μl of the

10   antigen/adjuvant preparation was injected at 4 sites in the back and flanks of each of the mice. Two weeks later the mice were boosted with an injection of 100 μl rat α_d I domain/HuIgG4 antigen (50 μg/mouse) previously emulsified in an equal volume of Freunds Incomplete Adjuvant (FIA). After two additional weeks, the mice were boosted with 50 μg antigen in 200 μl PBS injected intravenously.

15   To evaluate serum titers in the immunized mice, retro-orbital bleeds were performed on the animals ten days following the third immunization. The blood was allowed to clot and serum isolated by centrifugation. The serum was used in an immunoprecipitation on biotinylated (BIP) rat splenocytes. Serum from each mouse immunoprecipitated protein bands of expected molecular weight

20   for rat α_d and rat CD18. One mouse was selected for the fusion and was boosted a fourth time as described above for the third boost.

The hybridoma supernatants were screened by antibody capture, described as follows. Immulon 4 plates (Dynatech, Cambridge, Massachusetts) were coated at 4°C with 50 μl/well goat anti-mouse IgA, IgG or IgM (Organon

25   Teknika) diluted 1:5000 in 50 mM carbonate buffer, pH 9.6. Plates were washed 3X with PBS containing 0.05% Tween 20 (PBST) and 50 μl culture supernatant was added. After incubation at 37°C for 30 minutes, and washing as described above, 50 μl horseradish peroxidase-conjugated goat anti-mouse IgG9(Fc)

- 55 -

(Jackson ImmunoResearch, West Grove, Pennsylvania) diluted 1:3500 in PBST was added. Plates were incubated as described above and washed 4X with PBST. Immediately thereafter, $100\mu l$ substrate, containing 1 mg/ml o-phenylene diamine (Sigma) and 0.1 μl/ml 30% H_2O_2 in 100 mM citrate, pH4.5, was added. The color reaction was stopped after 5 minutes with the addition of 50 μl 15% H_2SO_4. Absorbance at 490 nm was read on a Dynatech plate reader.

Supernatant from antibody-containing wells was also analyzed by ELISA with immobilized rat α_d I domain/HuIgG4 fusion protein. An ELISA with HuIgG4 antibody coated plates served as a control for reactivity against the IgG fusion partner. Positive wells were selected for further screening by BIP on rat splenocyte lysates using techniques described below.

Biotinylation of Cell Surface Antigens

Rats were sacrificed by asphyxiation with CO_2 and spleens were removed using standard surgical techniques. Splenocytes were harvested by gently pushing the spleen through a wire mesh with a 3 cc syringe plunger in 20 mls RPMI. Cells were collected into a 50 ml conical tube and washed in the appropriate buffer.

Cells were washed three times in cold D-PBS and resuspended at a density of 10^8 to 10^9 cells in 40 ml PBS. Four mg of NHS-Biotin (Pierce) was added to the cell suspension and the reaction was allowed to continue for exactly 15 minutes at room temperature. The cells were pelleted and washed three times in cold D-PBS.

Cell Lysates

Cells were resuspended at a density of 10^8 cells/ml in cold lysis Buffer (1% NP40; 50 mM Tris-HCl, pH 8.0; 150 mM NaCl; 2 mM CaCl; 2 mM MgCl; 1:100 solution of pepstain, leupeptine, and aprotinin, added just before adding to cells; and 0.0001 g PMSF crystals, added just before adding to cells).

- 56 -

Lysates were vortexed for approximately 30 seconds, incubated for 5 minute at room temperature, and further incubated for 15 minutes on ice. Lysates were centrifuged for 10 minutes at 10,000 xg to pellet the insoluble material. Supernatant was collected into a new tube and stored at between 4°C and -20°C.

5   Immunoprecipitation

One ml cell lysate was precleared by incubation with 200 µl of a protein A sepharose slurry (Zymed) overnight at 4°C. Precleared lysate was aliquoted into Eppendorf tubes at 50 µl/tube for each antibody to be tested. Twenty-five µl of polyclonal serum or 100 to 500 µl of monoclonal antibody
10   supernatant were added to the precleared lysates and the resulting mixture incubated for 2 hours at 4°C with rotation. One hundred µl rabbit anti-mouse IgG (Jackson) bound to protein A sepharose beads in a PBS slurry was then added and incubation continued for 30 minutes at room temperature with rotation. Beads were pelleted with gentle centrifugation, and washed three times with cold
15   Wash Buffer (10 mM HEPES; 0.2 M NaCl; 1% Trition X-100). Supernatant was removed by aspiration, and 20 µl 2X SDS sample buffer containing 10% β-mercaptoethanol was added. The sample was boiled for 2 minutes in a water bath, and the sample loaded onto a 5% SDS PAGE gel. Following separation, the proteins were transferred to nitrocellulose at constant current overnight. The
20   nitrocellulose filters were blocked with 3% BSA in TBS-T for 1 hour at room temperature and the blocking buffer was removed. A 1:6000 dilution of Strepavidin-HRP conjugate (Jackson) in 0.1% BSA TBS-T was added and incubation continued for 30 minutes at room temperature. Filters were washed three times for 15 minutes each with TBS-T and autoradiographed using
25   Amersham's ECL kit according to manufacturer's suggested protocol.

- 57 -

Example 19

Isolation of Mouse cDNA Clones

Isolation of a mouse α_d homolog was attempted.

Cross-species hybridization was performed using two PCR-generated probes: a 1.5 kb fragment corresponding to bases 522 to 2047 from human clone 19A2 (SEQ ID NO: 1), and a 1.0 kb rat fragment which corresponds to bases 1900 to 2900 in human clone 19A2 (SEQ ID NO: 1). The human probe was generated by PCR using primer pairs designated ATM-2 and 9-10.1 set out in SEQ ID NOS: 38 and 39, respectively; the rat probe was generated using primer pairs 434L and 434R; set out in SEQ ID NOS: 34 and 35, respectively. Samples were incubated at 94°C for 4 minutes and subjected to 30 cycles of the temperature step sequence: 94°C; 50°C 2 minutes; 72°C, 4 minutes.

5´-GTCCAAGCTGTCATGGGCCAG-3´   (SEQ ID NO: 38)

5´-GTCCAGCAGACTGAAGAGCACGG-3´   (SEQ ID NO: 39)

The PCR products were purified using the Qiagen Quick Spin kit according to manufacturer's suggested protocol, and approximately 180 ng DNA was labeled with 200 μCi [^{32}P]-dCTP using a Boehringer Mannheim Random Primer Labeling kit according to manufacturer's suggested protocol. Unincorporated isotope was removed using a Centri-sep Spin Column (Princeton Separations, Adelphia, NJ) according to manufacturer's suggested protocol. The probes were denatured with 0.2 N NaOH and neutralized with 0.4 M Tris-HCl, pH 8.0, before use.

A mouse thymic oligo dT-primed cDNA library in lambda ZAP II (Stratagene) was plated at approximately 30,000 plaques per 15 cm plate. Plaque lifts on nitrocellulose filters (Schleicher & Schuell, Keene, NH) were incubated at 50°C with agitation for 1 hour in a prehybridization solution (8 ml/lift) containing 30% formamide. Labeled human and rat probes were added to the

- 58 -

prehybridization solution and incubation continued overnight at 50°C. Filters were washed twice in 2X SSC/0.1% at room temperature, once in 2X SSC/0.1% SDS at 37°C, and once in 2X SSC/0.1% SDS at 42°C. Filters were exposed on Kodak X-Omat AR film at -80°C for 27 hours with an intensifying screen.

5   Four plaques giving positive signals on duplicate lifts were restreaked on LB medium with magnesium (LBM)/carbenicillin (100 mg/ml) plates and incubated overnight at 37°C. The phage plaques were lifted with Hybond filters (Amersham), probed as in the initial screen, and exposed on Kodak X-Omat AR film for 24 hours at -80°C with an intensifying screen.

10   Twelve plaques giving positive signals were transferred into low Mg^{++} phage diluent containing 10 mM Tris-HCl and 1 mM MgCl$_2$. Insert size was determined by PCR amplification using T3 and T7 primers (SEQ ID NOS: 13 and 14, respectively) and the following reaction conditions. Samples were incubated at 94°C for 4 minutes and subjected to 30 cycles of the temperature

15   step sequence: 94°C, for 15 seconds; 50°C, for 30 seconds; and 72°C for 1 minute.

            Six samples produced distinct bands that ranged in size from 300 bases to 1 kb. Phagemids were released via co-infection with helper phage and recircularized to generate Bluescript SK⁻ (Stratagene). The resulting colonies

20   were cultured in LBM/carbenicillin (100 mg/ml) overnight. DNA was isolated with a Promega Wizard miniprep kit (Madison, WI) according to manufacturer's suggested protocol. EcoRI restriction analysis of purified DNA confirmed the molecular weights which were detected using PCR. Insert DNA was sequenced with M13 and M13 reverse.1 primers set out in SEQ ID NOS: 40 and 41,

25   respectively.

          5´-TGTAAAACGACGGCCAGT-3´   (SEQ ID NO: 40)

          5´-GGAAACAGCTATGACCATG-3´   (SEQ ID NO: 41)

- 59 -

Sequencing was performed as described in Example 4.

Of the six clones, only two, designated 10.3-1 and 10.5-2, provided sequence information and were identical 600 bp fragments. The 600 bp sequence was 68% identical to a corresponding region of human α_d, 40% identical to

5   human CD11a, 58% identical to human CD11c, and 54% identical to mouse CD11b. This 600 bp fragment was then utilized to isolate a more complete cDNA encoding a putative mouse α_d homolog .

A mouse splenic cDNA library (oligo dT⁻ and random-primed) in lambda Zap II (Stratagene) was plated at 2.5 x 10^4 phage/15 cm LBM plate.

10   Plaques were lifted on Hybond nylon transfer membranes (Amersham), denatured with 0.5 M NaOH/1.5 M NaCl, neutralized with 0.5 M Tris Base/1.5 M NaCl/11.6 HCl, and washed in 2X SSC. The DNA was cross-linked to filters by ultraviolet irradiation.

Approximately 500,000 plaques were screened using probes 10.3-1

15   and 10.5-2 previously labeled as described *supra*. Probes were added to a prehybridization solution and incubated overnight at 50°C. The filters were washed twice in 2X SSC/0.1% SDS at room temperature, once in 2X SSC/0.1% SDS at 37°C, and once in 2X SSC/0.1% SDS at 42°C. Filters were exposed on Kodak X-Omat AR film for 24 hours at -80°C with an intensifying screen.

20   Fourteen plaques giving positive signals on duplicate lifts were subjected to a secondary screen identical to that for the initial screen except for additional final high stringency washes in 2X SSC/ 0.1% SDS at 50°C, in 0.5X SSC/0.1% SDS at 50°C, and at 55°C in 0.2X SSC/0.1% SDS. The filters were exposed on Kodak X-Omat AR film at -80°C for 13 hours with an intensifying screen.

25   Eighteen positive plaques were transferred into low Mg^{++} phage diluent and insert size determined by PCR amplification as described above. Seven of the samples gave single bands that ranged in size from 600 bp to 4 kb. *Eco*RI restriction analysis of purified DNA confirmed the sizes observed from

- 60 -

PCR and the DNA was sequenced with primers M13 and M13 reverse.1 (SEQ ID NOS: 40 and 41, respectively).

One clone designated B3800 contained a 4 kb insert which corresponded to a region 200 bases downstream of the 5´ end of the human α_d

5   19A2 clone and includes 553 bases of a 3´ untranslated region. Clone B3800 showed 77% identity to a corresponding region of human α_d, 44% identity to a corresponding region of human CD11a, 59% identity to a corresponding region of human CD11c, and 51% identity to a corresponding region of mouse CD11b. The second clone A1160 was a 1.2 kb insert which aligned to the 5´ end of the

10   coding region of human α_d approximately 12 nucleic acids downstream of the initiating methionine. Clone A1160 showed 75% identity to a corresponding region of human α_d, 46% identity to a corresponding region of human CD11a, 62% identity to a corresponding region of human CD11c, and 66% identity to a corresponding region of mouse CD11b.

15   Clone A1160, the fragment closer to the 5´ end of human clone 19A2, is 1160 bases in length, and shares a region of overlap with clone B3800 starting at base 205 and continuing to base 1134. Clone A1160 has a 110-base insertion (bases 704-814 of clone A1160) not present in the overlapping region of clone B3800. This insertion occurs at a probable exon-intron boundary [Fleming,

20   et al., J.Immunol. 150:480-490 (1993)] and was removed before subsequent ligation of clones A1160 and B3800.

Rapid Amplification of 5´ cDNA End of the Putative Mouse α_d Clone

RACE PCR [Frohman, "RACE: Rapid Amplification of cDNA Ends," in PCR Protocols: A Guide to Methods and Applications, Innis, et al.

25   (eds.) pp. 28-38, Academic Press:New York (1990)] was used to obtain missing 5´ sequences of the putative mouse α_d clone, including 5´ untranslated sequence and initiating methionine. A mouse splenic RACE-Ready kit (Clontech, Palo Alto, CA) was used according to the manufacturer's suggested protocol. Two

- 61 -

antisense, gene-specific primers, A1160 RACE1-primary and A1160 RACE2-nested (SEQ ID NOS: 42 and 43), were designed to perform primary and nested PCR.

5'-GGACATGTTCACTGCCTCTAGG-3'   (SEQ ID NO: 42)

5   5'-GGCGGACAGTCAGACGACTGTCCTG-3'   (SEQ ID NO: 43)

The primers, SEQ ID NOS: 42 and 43, correspond to regions starting 302 and 247 bases from the 5' end, respectively. PCR was performed as described, *supra*, using the 5' anchor primer (SEQ ID NO: 44) and mouse spleen cDNA supplied with the kit.

10   5'-CTGGTTCGGCCCACCTCTGAAGGTTCCAGAATCGAT (SEQ ID NO: 44)

Electrophoresis of the PCR product revealed a band approximately 280 bases in size, which was subcloned using a TA cloning kit (Invitrogen) according to manufacturer's suggested protocol. Ten resulting colonies were cultured, and the DNA isolated and sequenced. An additional 60 bases of 5' sequence were

15   identified by this method, which correspond to bases 1 to 60 in SEQ ID NO: 45.

Characteristics of the Mouse cDNA and Predicted Amino Acid Sequence

A composite sequence of the mouse cDNA encoding a putative homolog of human α_d is set out in SEQ ID NO: 45. Although homology between the external domains of the human and mouse clones is high, homology between

20   the cytoplasmic domains is only 30%. The observed variation may indicate C-terminal functional differences between the human and mouse proteins. Alternatively, the variation in the cytoplasmic domains may result from splice variation, or may indicate the existence of an additional β_2 integrin gene(s).

- 62 -

At the amino acid level, the mouse cDNA predicts a protein (SEQ ID NO: 46) with 28% identity to mouse CD11a, 53% identity to mouse CD11b, 28% identity to human CD11a, 55% identity to human CD11b, 59% identity to human CD11c, and 70% identity to human α_d. Comparison of the amino acid

5   sequences of the cytoplasmic domains of human α_d and the putative mouse homolog indicates regions of the same length, but having divergent primary structure. Similar sequence length in these regions suggests species variation rather than splice variant forms. When compared to the predicted rat polypeptide, Example 16, *supra*, mouse and rat cytoplasmic domains show greater than 60%

10   identity.

Example 20

Isolation of additional mouse αd cDNA clones for sequence verification

In order to verify the nucleic and amino acids sequences describe in Example 19 for mouse α_d, additional mouse sequences were isolated for the

15   purposes of confirmation.

Isolation of mouse cDNA by hybridization with two homologous α_d probes (3´ and 5´) was performed using both a mouse splenic random primed library and an oligo dT-primed cDNA library in lambda ZAP II (Strategene). The library was plated at 5×10^5 phage per 15 cm LBM plate. Plaques were

20   lifted on Hybond nylon membranes (Amersham), and the membranes were denatured (0.5 M NaOH/1.5 M NaCl), neutralized (0.5 M Tris Base/1.5 M NaCl / 11.6 M HCl) and washed (2X SSC salt solution). DNA was cross-lined to filters by ultraviolet irradiation.

Probes were generated using primers described below in a PCR

25   reaction under the following conditions. Samples were held at 94°C for 4 minutes and then run through 30 cycles of the temperature step sequence (94°C for 15 seconds; 50°C for 30 seconds; 72°C for 1 minute in a Perkin-Elmer 9600 thermocycler).

- 63 -

The 3´ probe was approximately 900 bases long and spanned a region from nucleotides 2752 to 3651 (in SEQ ID NO: 1) (5´ → 3´) and was produced with primers 11.b-1/2FOR11 and 11.b-1/2REV2 as shown in SEQ ID NOS: 69 and 74, respectively. This probe was used in a first set of lifts.

5   The 5´ probe was approximately 800 bases long and spanned a region from nucleotides 149 to 946 (in SEQ ID NO: 1) (5´ → 3´) and was produced with primers 11.b-1/2FOR1 and 11.a-1/1REV1 as shown in SEQ ID NOS: 50 and 85, respectively). This probe was used in a second set of lifts.

In a third set of lifts, both probes described above were used 10   together on the same plates.

Approximately 500,000 plaques were screened using the two probes from above which were labeled in the same way as described in Example 17. Labeled probes were added to a prehybridization solution, containing 45% formamide, and incubated overnight at 50°C. Filters were washed twice in 2X 15   SSC/0.1% SDS at room temperature (22°C). A final wash was carried out in 2X SSC/0.1% SDS at 50°C. Autoradiography was for 19 hours at -80°C on Kodak X-Omat AR film with an intensifying screen.

Thirteen plaques giving positive signals on at least duplicate lifts were subjected to a secondary screen performed as described for the initial screen 20   except that both the 3´ and 5´ labeled probes were used for hybridization and an additional final wash was incorporated using 2X SSC/0.1% SDS at 65´C. Autoradiography was performed as described above for 2.5 hours.

Thirteen plaques (designated MS2P1 through MS2P13) giving positive signals were transferred into low Mg^{++} phage diluent. Insert size was 25   determined by PCR amplification (Perkin-Elmer 9600 thermocycler) using T3 and T7 primers which anneal to Bluescript phagemid in ZAP II (sequence previously described) under the same conditions shown above. Band sizes ranged from 500 bases to 4Kb. Phagemids were isolated, prepared, and sequenced with M13 and M13 reverse.1 primers (SEQ ID NOS: 40 and 41, respectively). Five of the

- 64 -

thirteen clones; MS2P-3, MS2P-6, MS2P-9, MS2P-12, and MS2P-13, were sequenced, and together, represented a region from approximately base 200 at the 5´ end to about 300 bases past a first stop codon at the 3´ end.

Automated sequencing was performed as described in Example 4 by first using M13 and M13 reverse.1 primers (SEQ ID NOS: 40 and 41, respectively) to sequence the ends of each clone and to determine its position relative to construct #17 (SEQ ID NO: 45). Each clone was then completely sequenced using the appropriate primers (listed below) for that particular region.

11.b-1/2FOR1	5´-GCAGCCAGCTTCGGACAGAC-3´	(SEQ ID NO: 50)
11.a-1/1FOR2	5´-CCGCCTGCCACTGGCGTGTGC-3´	(SEQ ID NO: 60)

11.a-1/1REV1	5´-CTGGATGCTGCGAAGTGCTAC-3´	(SEQ ID NO: 85)
11.a-1/1REV2	5´-GCCTTGGAGCTGGACGATGGC-3´	(SEQ ID NO: 86)

Sequences were edited, aligned, and compared to a previously isolated mouse α_d sequence (construct #17, SEQ ID NO: 45).

Alignment of the new sequences revealed an 18 base deletion in construct #17 beginning at nucleotide 2308; the deletion did not cause a shift in the reading frame. Clone MS2P-9, sequenced as described above, also revealed the same 18 base deletion. The deletion has been observed to occur in 50% of mouse clones that include the region but has not been detected in rat or human α_d clones. The eighteen base deletion is characterized by a 12 base palindromic sequence AAGCAGGAGCTCCTGTGT (SEQ ID NO: 91). This inverted repeat in the nucleic acid sequence is self-complementary and may form a loop out, causing cleavage during reverse transcription. The mouse α_d sequence which includes the additional 18 bases is set forth in SEQ ID NO: 52; the deduced amino acid sequence is set forth in SEQ ID NO: 53.

- 66 -

Example 21

In situ hybridizations in Mouse

Tissue distribution was then determined for mouse α_d in order to provide a comparison to that in humans, described in Example 6.

5   A single stranded 200 bp mRNA probe was generated from a DNA template, corresponding to nucleotides 3460 to 3707 in the cytoplasmic tail region of the murine cDNA, by *in vitro* RNA transcription incorporating ^{35}S-UTP (Amersham).

Whole mouse embryos (harvested at days 11-18 after fertilization) 10   and various mouse tissues, including spleen, kidney, liver, intestine, and thymus, were hybridized *in situ* with the radiolabeled single-stranded mRNA probe.

Tissues were sectioned at 6 μm thickness, adhered to Vectabond (Vector Laboratories, Inc., Burlingame, CA) coated slides, and stored at -70°C. Prior to use, slides were removed from -70°C and placed at 50°C for 15   approximately 5 minutes. Sections were fixed in 4% paraformaldehyde for 20 minutes at 4°C, dehydrated with an increasing ethanol gradient (70-95-100%) for 1 minute at 4°C at each concentration, and air dried for 30 minutes at room temperature. Sections were denatured for 2 minutes at 70°C in 70% formamide/2X SSC, rinsed twice in 2X SSC, dehydrated with the ethanol gradient 20   described *supra* and air dried for 30 minutes. Hybridization was carried out overnight (12-16 hours) at 55°C in a solution containing ^{35}S-labeled riboprobes at 6 x 10^5 cpm/section and diethylpyrocarbonate (DEPC)-treated water to give a final concentration of 50% formamide, 0.3 M NaCl, 20 mM Tris-HCl, pH 7.5, 10% dextran sulfate, 1X Denhardt's solution, 100 mM dithiothreitol (DTT) and 25   5 mM EDTA. After hybridization, sections were washed for 1 hour at room temperature in 4X SSC/10 mM DTT, 40 minutes at 60°C in 50% formamide/2X SSC/10 mM DTT, 30 minutes at room temperature in 2X SSC, and 30 minutes at room temperature in 0.1X SSC. The sections were dehydrated, air dried for 2 hours, coated with Kodak NTB2 photographic emulsion, air dried for 2 hours,

- 67 -

developed (after storage at 4°C in complete darkness) and counterstained with hematoxylin/eosin.

Spleen tissue showed a strong signal primarily in the red pulp. This pattern is consistent with that of tissue macrophage distribution in the spleen, but
5   does not exclude other cell types.

Example 22

Generation of Mouse Expression Constructs

In order to construct an expression plasmid including mouse cDNA sequences exhibiting homology to human α_d, inserts from clones A1160 and
10   B3800 were ligated. Prior to this ligation, however, a 5′ leader sequence, including an initiating methionine, was added to clone A1160. A primer designated "5′ PCR leader" (SEQ ID NO: 47) was designed to contain: (1) identical nonspecific bases at positions 1-6 allowing for digestion; (2) a BamHI site (underlined in SEQ ID NO: 47) from positions 7-12 to facilitate subcloning
15   into an expression vector; (3) a consensus Kozak sequence from positions 13-18, (4) a signal sequence including a codon for an initiating methionine (bold in SEQ ID NO: 47), and (5) an additional 31 bases of specifically overlapping 5′ sequence from clone A1160 to allow primer annealing. A second primer designated "3′ end frag" (SEQ ID NO: 48) was used with primer "5′ PCR
20   leader" to amplify the insert from clone A1160.

5′-AGTTAC<u>GGATCC</u>GGCACCATGAC-
            -CTTCGGCACTGTGATCCTCCTGTGTG-3′   (SEQ ID NO: 47)

5′-GCTGGACGATGGCATCCAC-3′   (SEQ ID NO: 48)

The resulting PCR product did not digest with BamHI, suggesting
25   that an insufficient number of bases preceded the restriction site, prohibiting

- 68 -

recognition by the enzyme. The length of the "tail" sequence preceding the *Bam*HI site in the 5´ primer (SEQ ID NO: 47) was increased and PCR was repeated on the amplification product from the first PCR. A 5´ primer, designated mAD.5´.2 (SEQ ID NO: 49), was designed with additional nonspecific

5   bases at positions 1-4 and an additional 20 bases specifically overlapping the previously employed "5´ PCR leader" primer sequences.

5´-GTAGAGTTAC<u>GGATCC</u>GGCACCAT-3´   (SEQ ID NO: 49)

Primers "mAD.5´.2" and "3´ end frag" were used together in PCR with the product from the first amplification as template. A resulting secondary

10   PCR product was subcloned into plasmid pCRtmII (Invitrogen) according to manufacturer's suggested protocol and transformed into competent One shot cells (Invitrogen). One clone containing the PCR product was identified by restriction enzyme analysis using *Bam*HI and *Eco*RI and sequenced. After the sequence was verified, the insert was isolated by digestion with *Bam*HI and *Eco*RI and gel

15   purified.

The insert from clone B3800 was isolated by digestion with *Eco*RI and *Not*I, gel purified, and added to a ligation reaction which included the augmented A1160 *Bam*HI/*Eco*RI fragment. Ligation was allowed to proceed for 14 hours at 14°C. Vector pcDNA.3 (Invitrogen), digested with *Bam*HI and *Not*I,

20   was added to the ligation reaction with additional ligase and the reaction was continued for another 12 hours. An aliquot of the reaction mixture was transformed into competent *E. coli* cells, the resulting colonies cultured, and one positive clone identified by PCR analysis with the primers 11.b-1/2FOR1 and 11.b-1/2REV11 (SEQ ID NOS: 50 and 51, respectively). These primers bridge

25   the A1160 and B3800 fragments, therefore detection of an amplification product indicates the two fragments were ligated. The sequence of the positive clone was

- 70 -

thymidine kinase encoding cassettes. Further analysis of this clone with an I domain probe (corresponding to nucleotides 454-1064 in SEQ ID NO: 45) indicated that the clone did not contain I domain encoding sequences.

Using the same I domain probe, the λFIXII genomic library was rescreened. Initially, six positive clones were detected, one of which remained positive upon secondary screening. DNA isolated from this clone reacted strongly in Southern analysis with an I domain probe. No reactivity was detected using the original 750 bp probe, however, indicating that this clone included regions 5′ to nucleotides 1985-2773 of SEQ ID NO: 45..

Alternatively, the lack of hybridization to the 750 bp probe may have suggested that the clone was another member of the integrin family of proteins. To determine if this explanation was plausible, the 13 kb insert was subcloned into pBluescript SKII$^+$. Purified DNA was sequenced using primers corresponding to α_d I domain nucleic acid sequences 441-461, 591-612, 717-739, and reverse 898-918 in SEQ ID NO: 52. Sequence information was obtained using only the first 4441-4461 primer, and only the 5′-most exon of the I domain was efficiently amplified. The remainder of the I domain was not amplified. The resulting clone therefore comprised exon 6 of the mouse α_d gene, and intronic sequences to the 3′ and 5′ end of the exon. Exon 7 was not represented in the clone. After sequencing, a construct is generated containing neomycin resistance and thymidine kinase genes.

The neomycin resistance (neo^r) gene is inserted into the resulting plasmid in a manner that interrupts the protein coding sequence of the genomic mouse DNA. The resulting plasmid therefore contains a neo^r gene within the mouse genomic DNA sequences, all of which are positioned within a thymidine kinase encoding region. Plasmid construction in this manner is required to favor homologous recombination over random recombination [Chisaka, *et al.*, *Nature* *355*:516-520 (1992)].

- 69 -

verified with the primers set out in SEQ ID NOS: 50 and 51, which amplify from base 100 to 1405 after the initiating methionine.

Example 23

Construction of a Knock-out Mouse

5   In order to more accurately assess the immunological role of the protein encoded by the putative mouse α_d cDNA, a "knock-out" mouse is designed wherein the genomic DNA sequence encoding the putative α_d homolog is disrupted by homologous recombination. The significance of the protein encoded by the disrupted gene is thereby assessed by the absence of the encoded 10   protein. Generation of "knock-out" mice is described in Deng, et al., Mol.Cell.Biol. 13:2134-2140 (1993).

Design of such a mouse begins with construction of a plasmid containing sequences to be "knocked out" by homologous recombination events. A 750 base pair fragment of the mouse cDNA (corresponding to nucleotides 1985 15   to 2733 in SEQ ID NO: 45) was used to identify a mouse genomic sequence encoding the putative mouse α_d homolog from a λFIXII genomic library. Primary screening resulted in 14 positive plaques, seven of which were confirmed by secondary screening. Liquid lysates were obtained from two of the plaques giving the strongest signal and the λ DNA was isolated by conventional methods. 20   Restriction mapping and Southern analysis confirmed the authenticity of one clone, designated 14-1, and the insert DNA was isolated by digestion with NotI. This fragment was cloned into Bluescript SKII$^+$.

In order to identify a restriction fragment of approximately 9 to 14 kb, a length reported to optimize the probability of homologous recombination 25   events, Southern hybridization was performed with the 750 bp cDNA probe. Prior to hybridization, a restriction map was constructed for clone 14-1. A 12 kb fragment was identified as a possible candidate and this fragment was subcloned into pBluescript SKII$^+$ in a position wherein the mouse DNA is flanked by

- 72 -

10^6 dpm/ml. ' Hybridization was carried out at 42°C for 16-18 hours. Filters were washed extensively in 2X SSPE/0.1% SDS at room temperature and exposed to X-ray film to visualize any hybridizing plaques.

Two clones with significant sequence homology to human α_d were
5   identified. Clone #2 was approximately 800 bp in length and mapped to the 5´ end of human α_d. Clone #2 includes an initiating methionine and complete leader sequence. Clone #7 was approximately 1.5 kb and includes an initiating methionine. The 5´ end of clone #7 overlapped that of clone #2, while the 3´ sequences terminated at a point beyond the I domain sequences. Internal
10 sequencing of clone #7 is performed using the nested deletions sequencing technique.

The predicted N terminal amino acid sequence for rabbit α_d as determined from clones #2 and #7 indicated a protein with 73% identity with human α_d , 65% identity with mouse α_d, and 58% identity with mouse CD11b,
15 human CD11b, and human CD11c. The nucleic acid sequence for clone #2 is set out in SEQ ID NO: 92; the predicted amino acid sequence is set out in SEQ ID NO: 93

Isolation of a full length rabbit α_d cDNA is carried out using labeled rabbit fragment, clone #7, and rescreening the cDNA library from which
20 the fragment was derived.

Isolation of a rabbit α_d clone allows expression of the protein, either on the surface of transfectants or as a soluble full length or truncated form. This protein is then used as an immunogen for the production of monoclonal antibodies for use in rabbit models of human disease states.

- 71 -

Example 24

Cloning of Rabbit α_d - Construction and Screening of the Rabbit cDNA Library

Identification of human α_d homologs in rats and mice led to the investigation of the existence of a rabbit homolog which would be useful in rabbit
5   models of human disease states described *infra*.

Poly A$^+$ RNA was prepared from a whole rabbit spleen using an Invitrogen FastTrack kit (San Diego, CA) according to manufacturer's suggested protocol and reagents supplied with the kit. From 1.65 g tissue, 73 μg poly A$^+$RNA were isolated. The rabbit spleen RNA was used to construct a ZAP
10   Express cDNA library using a kit from Stratagene (La Jolla, CA). Resulting cDNA was directionally cloned into *EcoRI* and *XhoI* sites in the lambda arms of a pBK-CMV phagemid vector. Gigapack II Gold (Stratagene) was used to package the lambda arms into phage particles. The resulting library titer was estimated to be approximately 8×10^5 particles, with an average insert size of 1.2
15   kb.

The library was amplified once by plating for confluent plaque growth and cell lysate was collected. The amplified library was plated at approximately 30,000 plaque forming units (pfu) per 150 mm plate with *E. coli* and the resulting mixture incubated for 12-16 hrs at 37°C to allow plaque
20   formation. Phage DNA was transferred onto Hybond N$^+$ nylon membranes (Amersham, Arlington Heights, Illinois). The membranes were hybridized with a mixture of two random primed radiolabeled mouse α_d PCR DNA probes. The first probe was generated from a PCR product spanning nucleotides 149-946 in SEQ ID NO: 52. The second probe was from a PCR product spanning
25   nucleotides 2752-3651 in SEQ ID NO: 52. Probes were labeled by random priming (Boehringer Mannheim Random Primed DNA Labeling Kit) and the reaction mixture was passed over a Sephadex G-50 column to remove unincorporated nucleotides. The hybridization solution was composed of 5X SSPE, 5X Denhardts, 1% SDS, 40% Formamide and the labeled probes at 1 x

- 74 -

functions which damage normal host tissue through either specific autoimmune responses or as a result of bystander cell damage.

Disease states in which there is evidence of macrophages playing a significant role in the disease process include multiple sclerosis, arthritis, graft
5   atherosclerosis, some forms of diabetes and inflammatory bowel disease. Animal models, discussed below, have been shown to reproduce many of the aspects of these human disorders. Inhibitors of α_d function are tested in these model systems to determine if the potential exists for treating the corresponding human diseases.

10   A. Graft Arteriosclerosis

Cardiac transplantation is now the accepted form of therapeutic intervention for some types of end-state heart disease. As the use of cyclosporin A has increased one year survival rates to 80%, the development of progressive graft arteriosclerosis has emerged as the leading cause of death in cardiac
15   transplants surviving beyond the first year. Recent studies have found that the incidence of significant graft arteriosclerosis 3 years following a cardiac transplant is in the range of 36-44% [Adams, *et al.*, *Transplantation 53*:1115-1119 (1992); Adams, *et al.*, *Transplantation 56*:794-799 (1993)].

Graft arteriosclerosis typically consists of diffuse, occlusive, intimal
20   lesions which affect the entire coronary vessel wall, and are often accompanied by lipid deposition. While the pathogenesis of graft arteriosclerosis remains unknown, it is presumably linked to histocompatibility differences between donor and recipient, and is immunologic in nature. Histologically, the areas of intimal thickening are composed primarily of macrophages, although T cells are
25   occasionally seen. It is therefore possible that macrophages expressing α_d may play a significant role in the induction and/or development of graft arteriosclerosis. In such a case, monoclonal antibodies or small molecule inhibitors (for example, soluble ICAM-R) of α_d function could be given

- 73 -

Example 25

Animal Models For Determining α_d Therapeutic Utility

Immunohistologic data in dog and *in situ* hybridization in rats and mice has determined that in spleen α_d is expressed primarily by macrophages
5   present in red pulp and in lymph nodes, α_d is found in medullary cords and sinuses. The expression pattern is remarkably similar to what has been reported for two murine antigens defined by the monoclonal antibodies F4/80 and SK39. While biochemical characterization of these murine antigens has demonstrated that they are distinct from α_d, it is highly probably that α_d defines the same
10   macrophage subset as the murine F4/80 and SK39 antigens.

In mouse, SK39-positive macrophages have been identified in splenic red pulp where they may participate in the clearance of foreign materials from circulation, and in medulla of lymph nodes [Jutila, *et al.*, *J.Leukocyte Biol.* 54:30-39 (1993)]. SK39-positive macrophages have also been reported at sites of
15   both acute and chronic inflammation. Furthermore, monocytes recruited to thioglycolate-inflamed peritoneal cavities also express the SK39 antigen. Collectively, these findings suggest that, if SK39$^+$ cells are also $\alpha_d{}^+$, then these cells are responsible for the clearance of foreign materials in the spleen and participate in inflammation where macrophages play a significant role.

20   While the function of α_d remains unclear, other more well characterized β_2 integrins have been shown to participate in a wide variety of adhesion events that facilitate cell migration, enhance phagocytosis, and promote cell-cell interactions, events which all lead to upregulation of inflammatory processes. Therefore, it is highly plausible that interfering with the normal α_d
25   function may also interfere with inflammation where macrophages play a significant role. Such an anti-inflammatory effect could result from: i) blocking macrophage recruitment to sites of inflammation, ii) preventing macrophage activation at the site of inflammation or iii) interfering with macrophage effector

lumenal surface of the ascending aorta [Rosenfeld, *et al.*, *Arteriosclerosis* 7:9-23 (1987); Rosenfeld, *et al.*, *Arteriosclerosis* 7:24-34 (1987)]. The atherosclerotic lesions seen in these rabbits are simmer to those in humans. Lesions contain large numbers of T cells, most of which express CD45RO, a marker associated with memory T cells. Approximately half of the infiltrating T cells also express MHC class II antigen and some express the IL-2 receptor suggesting that many of the cells are in an activated state.

One feature of the atherosclerotic lesions found in cholesterol fed rabbits, but apparently absent in rodent models, is the accumulation of foam cell-rich lesions. Foam cell macrophages are believed to result from the uptake of oxidized low-density lipoprotein (LDL) by specific receptors. Oxidized LDL particles have been found to be toxic for some cell types including endothelial cells and smooth muscle cells. The uptake of potentially toxic, oxidized LDL particles by macrophages serves as an irritant and drives macrophage activation, contributing to the inflammation associated with atherosclerotic lesions.

Once monoclonal antibodies have been generated to rabbit α_d, cholesterol fed rabbits are treated. Treatments include prophylactic administration of α_d monoclonal antibodies or small molecule inhibitors, to demonstrate that α_d^+ macrophages are involved in the disease process. Additional studies would demonstrate that monoclonal antibodies to α_d or small molecule inhibitors are capable of reversing vessel damage detected in rabbits fed an atherogenic diet.

C. Insulin-dependent Diabetes

BB rats spontaneously develop insulin-dependent diabetes at 70-150 days of age. Using immunohistochemistry, MHC class II$^+$, ED1$^+$ macrophages can be detected infiltrating the islets early in the disease. Many of the macrophages appear to be engaged in phagocytosis of cell debris or normal cells. As the disease progresses, larger numbers of macrophages are found infiltrating

- 75 -

prophylactically to individuals who received heart transplants and are at risk of developing graft arteriosclerosis.

Although atherosclerosis in heart transplants presents the greatest threat to life, graft arteriosclerosis is also seen in other solid organ transplants, 5   including kidneys and livers. Therapeutic use of α_d blocking agents could prevent graft arteriosclerosis in other organ transplants and reduce complications resulting from graft failure.

One model for graft arteriosclerosis in the rat involves heterotopic cardiac allografts transplanted across minor histocompatibility barriers. When 10   Lewis cardiac allografts are transplanted into MHC class I and II compatible F-344 recipients, 80% of the allografts survive at least 3 weeks, while 25% of the grafts survive indefinitely. During this low-grade graft rejection, arteriosclerosis lesions form in the donor heart. Arterial lesions in 120 day old allografts typically have diffuse fibrotic intimal thickening indistinguishable in appearance 15   from graft arteriosclerosis lesions found in rejecting human cardiac allografts.

Rats are transplanted with hearts mismatched at minor histocompatibility antigens, for example Lewis into F-344. Monoclonal antibodies specific for rat α_d or small molecule inhibitors of α_d are given periodically to transplant recipients. Treatment is expected to reduce the incidence of graft 20   arteriosclerosis in non-rejecting donor hearts. Treatment of rats with α_d monoclonal antibodies or small molecule inhibitors may not be limited to prophylactic treatments. Blocking α_d function is also be expected to reduce macrophage mediated inflammation and allow reversal of arterial damage in the graft.

25   B. Atherosclerosis in Rabbits Fed Cholesterol

Rabbits fed an atherogenic diet containing a cholesterol supplement for approximately 12-16 weeks develop intimal lesions that cover most of the

- 77 -

the islets, although significant numbers of T cells, and later B cells, also appear to be recruited to the site [Hanenberg, *et al.*, *Diabetologia 32*:126-134 (1989)].

Development of diabetes in BB rats appears to depend on both early macrophage infiltration and subsequent T cells recruitment. Treatment of BB rats with silica particles, which are toxic to macrophages, has been effective in blocking the early macrophage infiltration of the islets. In the absence of early macrophage infiltration, subsequent tissue damage by an autoaggressive lymphocyte population fails to occur. Administration of monoclonal antibody OX-19 (specific for rat CD5) or monoclonal antibody OX-8 (specific for rat CD8), which block the T cell-associated phase of the disease, is also effective in suppressing the development of diabetes.

The central role of macrophages in the pathology of this model makes it attractive for testing inhibitors of α_d function. Rats genetically predisposed to the development of insulin-dependent diabetes are treated with monoclonal antibodies to α_d or small molecule inhibitors and evaluated for the development of the disease. Preventing or delaying clinical onset is evidence that α_d plays a pivotal role in macrophage damage to the islet cells.

D.   Inflammatory Bowel Disease (Crohn's Disease, Ulcerative Colitis)

Animal models used in the study of inflammatory bowel disease (IBD) are generally elicited by intrarectal administration of noxious irritants (e.g. acetic acid or trinitrobenzene sulfonic acid/ethanol). Colonic inflammation induced by these agents is the result of chemical or metabolic injury and lacks the chronic and spontaneously relapsing inflammation associated with human IBD. However, a recently described model using subserosal injections of purified peptidoglycan-polysaccharide (PG-PS) polymers from either group A or group D streptococci appears to be a more physiologically relevant model for human IBD [Yamada, *et al.*, *Gastroenterolgy 104*:759-771 (1993)].

- 78 -

In this model PG-PS is injected into the subserosal layer of the distal colon. The resulting inflammatory response is biphasic with an initial acute episode three days after injection, which is followed by a spontaneous chronic phase three to four weeks later. The late phase response is granulomatous in nature, and results in colonic thickening, adhesions, colonic nodules and mucosal lesions. In addition to mucosal injury, PG-PS colitis frequently leads to arthritis anemia and granulomatous hepatitis. The extraintestinal manifestations of the disease make the model attractive for studying Crohn's colitis in that a significant number of patients with active Crohn's disease suffer from arthritic joint disease and hepatobillary inflammation.

Granulomatous lesions are the result of chronic inflammation which leads to the recruitment and subsequent activation of cells of the monocyte/macrophage lineage. Presence of granulomatous lesions in Crohn's disease and the above animal model make this an attractive clinical target for α_d monoclonal antibodies or other inhibitors of α_d function. Inhibitors of α_d function are expected to block the formation of lesions associated with IBD or even reverse tissue damage seen in the disease.

E. Arthritis

Arthritis appears to be a multi-factorial disease process involving a variety of inflammatory cell types including neutrophils, T lymphocytes and phagocytic macrophages. Although a variety of arthritis models exist, preparations of streptococcal cell wall proteoglycan produce a disorder most similar to the human disease.

In rats, streptococcal cell wall induces inflammation of peripheral joints characterized by repeated episodes of disease progression followed by remission and eventually resulting in joint destruction over a period of several months [Cromartie, et al., J.Exp.Med. 146:1585-1602 (1977); Schwab et al., Infection and Immunity 59:4436-4442 (1991)]. During the chronic phase of the

- 79 -

disease, mononuclear phagocytes or macrophages are believed to play a major role in destruction of the synovium. Furthermore, agents which suppress the recruitment of macrophages into the synovium effectively reduce the inflammation and pathology characteristic of arthritis.

5   A central role for the macrophage in synovium destruction that leads to arthritis predicts that monoclonal antibodies to α_d or inhibitors of α_d function may have therapeutic potential in the treatment of this disease. As in other models previously described, α_d monoclonal antibodies or small molecule inhibitors administered prophylactically are expected to block or moderate joint

10   inflammation and prevent destruction of the synovium. Agents that interfere with α_d function may also moderate ongoing inflammation by preventing the recruitment of additional macrophages to the joint or blocking macrophage activation. The net result would be to reverse ongoing destruction of the joint and facilitate tissue repair.

15   F. Multiple Sclerosis
           Although pathogenesis of multiple sclerosis (MS) remains unclear, it is generally accepted that the disease is mediated by $CD4^+$ T cells which recognize autoantigens in the central nervous system and initiate an inflammatory cascade. The resulting immune response results in the recruitment of additional

20   inflammatory cells, including activated macrophages which contribute to the disease. Experimental autoimmune encephalomyelitis (EAE) is an animal model which reproduces some aspects of MS. Recently, monoclonal antibodies reactive with CD11b/CD18 [Huitinga, et al., Eur.J.Immunol. 23:709-715 (1993)] present on inflammatory macrophages have been shown to block both clinical and

25.   histologic disease. The results suggest that monoclonal antibodies or small molecule inhibitors to α_d are likely to be effective in blocking the inflammatory response in EAE. Such agents also have important therapeutic applications in the treatment of MS.

- 80 -

Numerous modifications and variations in the invention as set forth in the above illustrative examples are expected to occur to those skilled in the art. Consequently only such limitations as appear in the appended claims should be placed on the invention.

(2) INFORMATION FOR SEQ ID NO:4:

   (i) SEQUENCE CHARACTERISTICS:
      (A) LENGTH: 1163 amino acids
      (B) TYPE: amino acid
      (C) STRANDEDNESS: single
      (D) TOPOLOGY: linear

   (ii) MOLECULE TYPE: protein

   (xi) SEQUENCE DESCRIPTION: SEQ ID NO:4:

(2) INFORMATION FOR SEQ ID NO:54:

    (i) SEQUENCE CHARACTERISTICS:
        (A) LENGTH: 3597 base pairs
        (B) TYPE: nucleic acid
        (C) STRANDEDNESS: single
        (D) TOPOLOGY: linear

    (ii) MOLECULE TYPE: cDNA

    (ix) FEATURE:
        (A) NAME/KEY: CDS
        (B) LOCATION: 40..3525

WHAT IS CLAIMED IS:

1. A purified and isolated α_d polynucleotide consisting essentially of human α_d protein coding sequence set out in SEQ ID NO: 1.

2. The polynucleotide of claim 1 which is a DNA molecule.

3. The DNA molecule of claim 2 which is a cDNA molecule.

4. The DNA molecule of claim 2 which is a genomic DNA molecule.

5. The DNA molecule of claim 2 which is a wholly or partially chemically synthesized DNA molecule.

6. A full length purified and isolated α_d-encoding polynucleotide selected from the group consisting of:

a) the human DNA sequence set out in SEQ ID NO: 1, and

b) a DNA molecule which hybridizes under stringent conditions to the noncoding strand of the protein coding portion of the DNA of a).

7. A DNA molecule encoding the human α_d amino acid sequence set out in SEQ ID NO: 2.

8. A DNA expression construct comprising a DNA molecule according to claim 2.

9. A host cell transformed with a DNA molecule according to claim 2.

- 160 -

10. A method for producing an α_d polypeptide comprising growing a host cell according to claim 9 in a suitable medium and isolating α_d polypeptide from said host cell or the medium of its growth.

11. Purified and isolated α_d polypeptide consisting essentially of the human α_d amino acid sequence set out in SEQ ID NO: 2.

12. A polypeptide capable of specifically binding to α_d.

13. A polypeptide according to claim 12 which is an antibody.

14. An antibody according to claim 13 which is a monoclonal antibody.

15. An anti-idiotype antibody specific for the monoclonal antibody of claim 14.

16. A hybridoma cell line producing the monoclonal antibody according to claim 14.

17. A purified and isolated α_d extracellular domain polypeptide fragment comprising amino acids 17 to 1108 of the human α_d amino acid sequence set out in SEQ ID NO: 2.

18. A purified and isolated α_d I domain polypeptide fragment comprising amino acids 145 to 355 of the human α_d amino acid sequence set out in SEQ ID NO: 2.

- 161 -

19.   A fusion protein comprising α_d extracellular domain polypeptide amino acids 17 to 1108 of SEQ ID NO: 2 and human immunoglobulin constant domain sequences.

20.   A purified and isolated murine polynucleotide consisting essentially of the α subunit protein coding sequence set out in SEQ ID NO: 45.

21.   A method for isolating a polynucleotide encoding a protein that binds to α_d comprising the steps of:

a) transforming or transfecting appropriate host cells with a DNA construct comprising a reporter gene under the control of a promoter regulated by a transcription factor having a DNA-binding domain and an activating domain;

b) expressing in said host cells a first hybrid DNA sequence encoding a first fusion of part or all of α_d and either the DNA binding domain or the activating domain of said transcription factor;

c) expressing in said host cells a library of second hybrid DNA sequences encoding second fusions of part or all of putative α_d binding proteins and the DNA binding domain or activating domain of said transcription factor which is not incorporated in said first fusion;

d) detecting binding of an α_d binding protein to α_d in a particular host cell by detecting the production of reporter gene product in said host cell; and

e) isolating second hybrid DNA sequences encoding α_d binding protein from said particular host cell.

22.   A method for identifying a compound capable of reacting specifically with α_d and of modulating the interaction of binding partners α_d and ICAM-R comprising the steps of:

- 162 -

a) immobilizing α_d or a fragment thereof, or ICAM-R or a fragment thereof, on a solid support coated or impregnated with a fluorescent agent;

b) labelling the non-immobilized binding partner with a compound capable of exciting said fluorescent agent;

c) contacting said immobilized binding partner with said labelled binding partner in the presence and absence of a putative modulator compound capable of specifically reacting with α_d;

d) detecting light emission by said fluorescent agent; and

e) identifying modulating compounds as those compounds that affect the emission of light by said fluorescent agent in comparison to the emission of light by said fluorescent agent in the absence of said modulating compound.

23. A purified and isolated α_d extracellular domain polypeptide fragment comprising about amino acid 127 to about amino acid 353 of the human α_d amino acid sequence set out in SEQ ID NO: 2.

24. A fusion protein comprising the polypeptide fragment of claim 23 and human immunoglobulin constant region sequences.

25. A purified and isolated α_d extracellular domain polypeptide fragment comprising about amino acid 17 to about amino acid 603 of the human α_d amino acid sequence set out in SEQ ID NO: 2.

26. A fusion protein comprising the polypeptide fragment of claim 25 and human immunoglobulin constant region sequences.

- 163 -

27. A purified and isolated α_d extracellular domain polypeptide fragment comprising about amino acid 17 to about about amino acid 1029 of the human α_d amino acid sequence set out in SEQ ID NO: 2.

28. A fusion protein comprising the polypeptide fragment of claim 27 and immunoglobulin constant region sequences.

29. A purified and isolated murine polynucleotide comprising the α subunit protein coding sequence as set out in SEQ ID NO: 52.

30. A purified and isolated α_d polypeptide consisting essentially of the murine α_d amino acid sequence set out in SEQ ID NO: 53.

31. A purified and isolated rat polynucleotide comprising the α subunit protein coding sequence as set out in SEQ ID NO: 54.

32. A purified and isolated α_d polypeptide consisting essentially of the rat α_d amino acid sequence set out in SEQ ID NO: 55.

33. A purified and isolated polypeptide fragment comprising extracellular domain sequences of the polypeptide of claim 32.

34. A polypeptide capable of specifically binding to the polypeptide of claim 32.

35. A polypeptide according to claim 34 which is an antibody.

36. An antibody according to claim 35 which is a monoclonal antibody.

- 164 -

37. A rodent that does not express a functional α_d protein.

38. A rodent that expresses a variant α_d protein.

INTERNATIONAL SEARCH REPORT

A. CLASSIFICATION OF SUBJECT MATTER

IPC(6) :Please See Extra Sheet.

US CL :Please See Extra Sheet.

According to International Patent Classification (IPC) or to both national classification and IPC

B. FIELDS SEARCHED

Minimum documentation searched (classification system followed by classification symbols)

U.S. : 435/6, 7.1, 69.1, 240.2, 252.3, 320.1; 530/350, 387.1, 387.2, 388.1, 388.22; 536/22.1, 23.1, 23.5

Documentation searched other than minimum documentation to the extent that such documents are included in the fields searched

None

Electronic data base consulted during the international search (name of data base and, where practicable, search terms used)

APS, BIOSIS, CAS ONLINE, STN

search terms: human beta2 integrin, leukointegrin, leu cam, leukocyte integrin#, alphad, integrin, alphas

C. DOCUMENTS CONSIDERED TO BE RELEVANT

Category*	Citation of document, with indication, where appropriate, of the relevant passages	Relevant to claim No.
A	CELL, Volume 72, issued 26 March 1993, Michishita et al., "A Novel Divalent Cation-Binding Site in the A Domain of the $\beta2$ Integrin CR3 (CD11b/CD18) Is Essential for Ligand Binding", pages 857-867, see entire document.	1-38
A	CELL, Volume 69, issued 03 April 1992, Hynes, "Integrins: Versatility, Modulation, and Signaling in Cell Adhesion", pages 11-25, see entire document.	1-38

[X] Further documents are listed in the continuation of Box C.   [ ]   See patent family annex.

*	Special categories of cited documents:	"T" later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention
"A"	document defining the general state of the art which is not considered to be of particular relevance	
"E"	earlier document published on or after the international filing date	"X" document of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone
"L"	document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)	
"O"	document referring to an oral disclosure, use, exhibition or other means	"Y" document of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art
"P"	document published prior to the international filing date but later than the priority date claimed	"&" document member of the same patent family

Date of the actual completion of the international search	Date of mailing of the international search report
11 APRIL 1995	17 APR 1995

Name and mailing address of the ISA/US	Authorized officer
Commissioner of Patents and Trademarks Box PCT Washington, D.C. 20231	Hyosuk Kim
Facsimile No. (703) 305-3230	Telephone No. (703) 308-0196

Form PCT/ISA/210 (second sheet)(July 1992)*

C (Continuation). DOCUMENTS CONSIDERED TO BE RELEVANT		
Category*	Citation of document. with indication. where appropriate, of the relevant passages	Relevant to claim No.
A	THE JOURNAL OF IMMUNOLOGY, Volume 150, Number 2, issued 13 January 1993, Fleming et al., "Structural Analysis of the *CD11b* Gene and Phylogenetic Analysis of the α-Integrin Gene Family Demonstrate Remarkable Conservation of Genomic Organization and Suggest Early Diversification during Evolution", pages 480-490, see entire document.	1-38
